Abstract— We consider the random graph induced by the random key predistribution scheme of Eschenauer and Gligor under the assumption of full visibility. We show the existence of a zero-one law for the absence of isolated nodes, and complement it by a Poisson convergence for the number of isolated nodes. Leveraging earlier results and analogies with Erdős-Renyi graphs, we explore similar results for the property of graph connectivity. Implications for secure connectivity are discussed.

Keywords: Wireless sensor networks, Key predistribution, Secure connectivity, Absence of isolated nodes, Zero-one laws, Poisson convergence.

I. INTRODUCTION

Wireless sensor networks (WSNs) are distributed collections of sensors with limited capabilities for computations and wireless communications. It is envisioned that such networks will be deployed in hostile environments where communications are monitored, and nodes are subject to capture and surreptitious use by an adversary. Under such circumstances, cryptographic protection will be needed to ensure secure communications, as well as sensor-capture detection, key revocation and sensor disabling. However, traditional key exchange and distribution protocols based on trusting third parties are inadequate for large-scale WSNs, e.g., see [7, 15, 17] for discussions of some of the challenges.

A. A random key predistribution scheme

Recently Eschenauer and Gligor [7] have proposed a key management solution better suited to WSN environments. This scheme, hereafter called the EG scheme, is based on *random* key predistribution and operates in three phases: Consider a collection of n sensor nodes equipped with wireless transmitters, and assume available a large set of P cryptographic keys, also known as the *key pool*.

- (i) Initialization phase: Before network deployment, each node randomly selects a set of K *distinct* keys from the pool. These

This report is an extended version of the submission [18]. Some of the notation has been changed and embarrassing mistakes have been caught!

K keys form the *key ring* of the node, and are inserted into its memory. Key rings are selected independently across nodes.

- (ii) Key setup phase: After deployment, each node discovers its *wireless neighbors*, i.e., nodes which are within its wireless communication range. When a node finds a wireless neighbor with whom it shares a key, they mutually authenticate the key to verify that the other party actually owns it. At the end of this phase, wireless neighbors which have keys in common can now communicate securely with each other in one hop.
- (iii) Path-key identification phase: The key rings being randomly selected, there is a possibility that some pairs of wireless neighbors may not share a key. If a path made up of nodes sharing keys pairwise exists between such a pair of wireless neighbors, this (secure) path can be used to exchange a *path-key* to establish a direct (and secure) link between them.

B. Dimensioning for secure connectivity

A basic question concerning the EG scheme is its ability to achieve *secure connectivity* among participating nodes in the sense that a *secure path* exists between any pair of nodes. Given the randomness involved, for any pair of integers P and K such that $K < P$, there is a positive probability that secure connectivity will *not* be achieved – This will be so even in the best of cases when the communication graph is itself connected.¹ Hence, there arises the need to understand how to select the parameters P and K in order to make the probability of secure connectivity as large as possible.

This issue was addressed by Eschenauer and Gligor in their original paper under two simplifying assumptions, namely *full visibility* and *mutual independence* of secure link allocations; more on this second assumption in Section III. Full visibility refers to the situation where two nodes are always able to communicate with each other, irrespective of their relative positions or the quality of the wireless links that may exist between them. In that case, the shared key discovery process allows every pair of nodes to determine whether their key rings have keys in common. This makes it possible to model

¹The communication graph refers to the graph induced by the communication process whereby two nodes are adjacent if they are wireless neighbors, e.g., the disk model or the SINR graph.

the EG scheme by the random graph $\mathbb{K}(n; P, K)$, introduced in Section II and hereafter referred to as the *random key graph*.

For sure, the assumption of full visibility does away with the wireless nature of the communication infrastructure supporting WSNs. However, in return this simplification allows us to focus on how randomizing key selections affects the establishment of secure links. It is this aspect of the EG scheme that we study here, as we develop various properties for the random key graph. We do so with an eye towards understanding how proper parameter selection in the EG scheme may lead to secure connectivity with very high probability.

C. Contributions

For the class of random key graphs, we show the existence of a zero-one law for the absence of isolated nodes, and identify the corresponding critical thresholds; see Theorem 4.1. We complement this result by a Poisson convergence for the number of isolated nodes; see Theorem 4.4. These results already imply a zero law for the property of graph connectivity. Next, starting with earlier results by Di Pietro et al. [4], we leverage analogies with Erdős-Renyi graphs (and attending zero-one laws) to conjecture the form of zero-one laws for graph connectivity in random key graphs. We also give conditions for the corresponding “double exponential” result. Implications of these issues for secure connectivity can be found in Section III. The proofs for Theorems 4.1 and 4.4 are outlined in Sections V and X, respectively.

All the rvs under consideration are defined on the *same* probability triple $(\Omega, \mathcal{F}, \mathbb{P})$. For sequences $a, b : \mathbb{N}_0 \rightarrow \mathbb{R}_+$, we write $a_n \sim b_n$ as a shorthand for the asymptotic equivalence $\lim_{n \rightarrow \infty} \frac{a_n}{b_n} = 1$.

II. RANDOM KEY GRAPHS

The model is parametrized by three positive integers, namely the number n of nodes, the size P of the key pool and the size K of each key ring with $K < P$. To lighten the notation we often group the integers P and K into the ordered pair $\theta \equiv (P, K)$. With \mathcal{P} the set of cryptographic keys, let \mathcal{P}_K to denote the collection of all subsets of \mathcal{P} which contain exactly K elements – Obviously, with $|\mathcal{P}| = P$, we have $|\mathcal{P}_K| = \binom{P}{K}$.

For each node $i = 1, \dots, n$, let $\mathbf{K}_i(\theta)$ denote the random set of K distinct keys assigned to node i . We can think of $\mathbf{K}_i(\theta)$ as an \mathcal{P}_K -valued rv. Under the EG scheme, the rvs $\mathbf{K}_1(\theta), \dots, \mathbf{K}_n(\theta)$ are assumed to be *i.i.d.* rvs which are *uniformly* distributed over \mathcal{P}_K with

$$\mathbb{P}[\mathbf{K}_i(\theta) = S] = \left(\frac{P}{K}\right)^{-1}, \quad S \in \mathcal{P}_K \quad (1)$$

for all $i = 1, \dots, n$. This corresponds to selecting keys randomly and *without* replacement from the key pool.

The key set-up phase in the EG scheme suggests a natural notion of adjacency between nodes: Distinct nodes $i, j = 1, \dots, n$ are said to be adjacent if they share at least one key in their key rings, namely

$$\mathbf{K}_i(\theta) \cap \mathbf{K}_j(\theta) \neq \emptyset. \quad (2)$$

In that case, an undirected link is assigned between nodes i and j . The resulting graph with vertex set $\{1, \dots, n\}$ is hereafter denoted $\mathbb{K}(n; \theta)$. For distinct $i, j = 1, \dots, n$, it is a simple matter to check that

$$\mathbb{P}[\mathbf{K}_i(\theta) \cap \mathbf{K}_j(\theta) = \emptyset] = q(\theta) \quad (3)$$

with

$$q(\theta) := \frac{\binom{P-K}{K}}{\binom{P}{K}}. \quad (4)$$

Random key graphs form a subclass in the family of random graphs known in the literature as *random intersection* graphs, e.g., see [12, 16]. The model discussed here differs from the class of random graphs in these references where each node is assigned a key ring, one key at a time according to a Bernoulli-like mechanism (so that a key ring has a positive probability of being empty).

Despite strong similarities, we stress that the random graph $\mathbb{K}(n; \theta)$ is *not* an Erdős-Renyi graph $\mathbb{G}(n; p)$ [11] even if we use

$$p = 1 - q(\theta). \quad (5)$$

This is so because edge assignments are correlated in $\mathbb{K}(n; \theta)$ but independent in $\mathbb{G}(n; p)$: Indeed, define the edge assignment rvs as the indicators rvs given by

$$\xi_{ij}(\theta) := \mathbf{1}[\mathbf{K}_i(\theta) \cap \mathbf{K}_j(\theta) \neq \emptyset]$$

for distinct $i, j = 1, \dots, n$. Then, for distinct triplets $i, j, k = 1, \dots, n$, the rvs $\xi_{ij}(\theta)$, $\xi_{jk}(\theta)$ and $\xi_{ik}(\theta)$ are *not* mutually independent (although they are *pairwise* independent). For instance, it is easy to check that

$$\mathbb{P}[\xi_{ij}(\theta) = 0, \xi_{ik}(\theta) = 0] = \mathbb{P}[\xi_{ij}(\theta) = 0] \mathbb{P}[\xi_{ik}(\theta) = 0]$$

but

$$\begin{aligned} & \mathbb{P}[\xi_{ij}(\theta) = 0, \xi_{jk}(\theta) = 0, \xi_{ik}(\theta) = 0] \\ & \neq \mathbb{P}[\xi_{ij}(\theta) = 0] \mathbb{P}[\xi_{jk}(\theta) = 0] \mathbb{P}[\xi_{ik}(\theta) = 0]. \end{aligned}$$

Let $P^*(n; \theta)$ denote the probability that the random graph $\mathbb{K}(n; \theta)$ is connected, namely

$$P^*(n; \theta) := \mathbb{P}[\mathbb{K}(n; \theta) \text{ is connected}].$$

In the full visibility case assumed here, $P^*(n; \theta)$ coincides with the probability of secure connectivity mentioned earlier.

III. RELATED WORK

We wish to select P and K so that $P^*(n; \theta)$ is as large (i.e., as close to one) as possible. This issue naturally draws attention to zero-one laws for graph connectivity in random key graphs when P and K are appropriately scaled with n . Such zero-one laws are known to hold for Erdős-Renyi graphs $\mathbb{G}(n; p)$ ($0 < p < 1$) [6, 11]: Whenever

$$p_n \sim c \frac{\log n}{n} \quad (6)$$

for some $c > 0$, it holds that

$$\lim_{n \rightarrow \infty} \mathbb{P}[\mathbb{G}(n; p_n) \text{ is connected}] = \begin{cases} 0 & \text{if } 0 < c < 1 \\ 1 & \text{if } 1 < c. \end{cases} \quad (7)$$

However, given that such zero-one laws for random key graphs were not available to them, Eschenauer and Gligor instead replaced $\mathbb{K}(n; \theta)$ with the *proxy* Erdős-Renyi graph $\mathbb{G}(n; p)$ where p is given by (5), thereby leading to the approximation

$$P^*(n; \theta) \simeq \mathbb{P}[\mathbb{G}(n; 1 - q(\theta)) \text{ is connected}]. \quad (8)$$

An additional benefit of this approach lies in the availability of the celebrated “double exponential” result of Erdős and Renyi [2, 6]: For every scalar γ , it is well known that

$$\lim_{n \rightarrow \infty} \mathbb{P}[\mathbb{G}(n; p_{n,\gamma}) \text{ is connected}] = e^{-e^{-\gamma}} \quad (9)$$

with

$$p_{n,\gamma} = \frac{\log n}{n} + \frac{\gamma}{n}, \quad n = 2, 3, \dots \quad (10)$$

Thus, if we select P and K as functions of n , say P_n and K_n , so that

$$1 - q(\theta_n) = \frac{\log n}{n} + \frac{\gamma}{n}, \quad n = 2, 3, \dots \quad (11)$$

then a reasonable approximation in the form

$$P^*(n; \theta_n) \simeq e^{-e^{-\gamma}}$$

suggests itself for large n . A refinement of this approach, still based on the theory of Erdős-Renyi graphs, is given by Hwang and Kim [10] for the EG as well as for a number of other random key predistribution schemes, including schemes by Chan et al. [3] and by Du et al. [5].

In [4], Di Pietro et al. argue that edge assignments in the random key graph (2) are not mutually independent (as was already indicated earlier) but may in fact be strongly correlated for reasonable values of the parameters K and P . Therefore, an analysis based on Erdős-Renyi graphs may not provide a reliable guide for properly dimensioning the EG scheme. This prompted these authors to investigate the connectivity properties of random key graphs (*without* the independence assumption on edge assignment). They showed [4, Thm. 4.6] that for n large, the random key graph will be connected with very high probability if P_n and K_n are selected such that

$$P_n \geq n \quad \text{and} \quad \frac{K_n^2}{P_n} \sim c \frac{\log n}{n} \quad (12)$$

as soon as $c > 16$.

IV. THE RESULTS

What happens when $c \leq 16$? – This is where we pick up the trail: Ideally, for reasons that should be apparent from the discussion of Section III, one would like to establish a zero-one law for graph connectivity in random key graphs, together with the appropriate version of an attending “double exponential” result. In view of the results of Di Pietro et al., we expect such a zero-one law to hold in the form

$$\lim_{n \rightarrow \infty} P^*(n; \theta_n) = \begin{cases} 0 & \text{if } 0 < c < 1 \\ 1 & \text{if } 1 < c \end{cases} \quad (13)$$

whenever

$$\frac{K_n^2}{P_n} \sim c \frac{\log n}{n} \quad (14)$$

for some $c > 0$ (possibly with some additional conditions).

This is not too farfetched for the following reasons: First of all, the results in [4, Thm. 4.6] already confirm the one-law in the range $c > 16$. Next, although it is certainly true that random key graphs do not coincide with Erdős-Renyi graphs, they certainly appear to be somewhat related – In both cases the edge assignments are pairwise independent. Therefore, the zero-one law (6)-(7) for Erdős-Renyi graphs may be viewed as indirect additional support for the validity of (13) under (14). In fact, such a “transfer” is not without precedent: In the class of random intersection graphs studied by Singer et al. [12, 16], Fill et al. [8] have shown equivalence with Erdős-Renyi graphs in a strong sense for some asymptotic regime of interest.

In the present paper we report on results that further suggest the validity of (13) under (14). As with Erdős-Renyi graphs, we address the problem by considering the property that the random key graph $\mathbb{K}(n; \theta)$ contains no isolated nodes. Thus, we define

$$P(n; \theta) := \mathbb{P}[\mathbb{K}_n(\theta) \text{ contains no isolated nodes}].$$

Obviously, if the random key graph $\mathbb{K}(n; \theta)$ is connected, then it does not contain isolated nodes, whence

$$P^*(n; \theta) \leq P(n; \theta). \quad (15)$$

A. Zero-one laws

With any pair of functions $P, K : \mathbb{N}_0 \rightarrow \mathbb{N}$, we associate a function $\alpha : \mathbb{N}_0 \rightarrow \mathbb{R}$ through the relation

$$\frac{K_n^2}{P_n} = \frac{\log n + \alpha_n}{n}, \quad n = 1, 2, \dots \quad (16)$$

Just set

$$\alpha_n := n \frac{K_n^2}{P_n} - \log n, \quad n = 1, 2, \dots$$

A pair of functions $P, K : \mathbb{N}_0 \rightarrow \mathbb{N}$ is said to be *admissible* if $K_n < P_n$ for all $n = 1, 2, \dots$. Our main result is the following zero-one law for the absence of isolated nodes.

Theorem 4.1: *For any admissible pair of functions $P, K : \mathbb{N}_0 \rightarrow \mathbb{N}$, it holds that*

$$\lim_{n \rightarrow \infty} P(n; \theta_n) = \begin{cases} 0 & \text{if } \lim_{n \rightarrow \infty} \alpha_n = -\infty \\ 1 & \text{if } \lim_{n \rightarrow \infty} \alpha_n = +\infty \end{cases} \quad (17)$$

where the function $\alpha : \mathbb{N}_0 \rightarrow \mathbb{R}$ is determined through (16).

A proof of Theorem 4.1 is outlined in Section V. Theorem 4.1 readily implies the following zero-one law.

Corollary 4.2: *Consider an admissible pair of functions $P, K : \mathbb{N}_0 \rightarrow \mathbb{N}$ such that (14) holds for some $c > 0$. Then it holds that*

$$\lim_{n \rightarrow \infty} P(n; \theta_n) = \begin{cases} 0 & \text{if } 0 < c < 1 \\ 1 & \text{if } 1 < c. \end{cases} \quad (18)$$

Indeed, it suffices to use Theorem 4.1 with any admissible pair of functions $P, K : \mathbb{N}_0 \rightarrow \mathbb{N}$ whose function $\alpha : \mathbb{N}_0 \rightarrow \mathbb{R}$ satisfies

$$\alpha_n = (c - 1)(1 + o(1)) \cdot \log n, \quad n = 1, 2, \dots$$

With the help of (15), it is now plain from Corollary 4.2 under (14) that

$$\lim_{n \rightarrow \infty} P^*(n; \theta_n) = 0 \quad \text{if } 0 < c < 1. \quad (19)$$

This already establishes the zero-law in (13) under (14). In fact, Theorem 4.1 already implies the stronger statement

$$\lim_{n \rightarrow \infty} P^*(n; \theta_n) = 0 \quad \text{if } \lim_{n \rightarrow \infty} \alpha_n = -\infty.$$

Taking our cue from existing results for Erdős-Renyi graphs [2, 6, 11] (as well as for geometric random graphs, e.g., see [9, 14]), we expect that again for random key graphs, graph connectivity and the absence of isolated nodes are *asymptotically equivalent* graph properties (for large n). This leads to the following conjecture which is currently under investigation:

Conjecture 4.3: *For any admissible pair of functions $P, K : \mathbb{N}_0 \rightarrow \mathbb{N}$, it holds that*

$$\lim_{n \rightarrow \infty} P^*(n; \theta_n) = \begin{cases} 0 & \text{if } \lim_{n \rightarrow \infty} \alpha_n = -\infty \\ 1 & \text{if } \lim_{n \rightarrow \infty} \alpha_n = +\infty \end{cases} \quad (20)$$

with function $\alpha : \mathbb{N}_0 \rightarrow \mathbb{R}$ determined through (16).

As before, by virtue of (15), the zero-law in Conjecture 4.3 readily follows from Theorem 4.1.

B. Poisson convergence

Stronger results can be contemplated: Consider $\theta = (P, K)$ with positive integers K and P such that $K < P$. Fix $n = 2, 3, \dots$ and write

$$\chi_{n,i}(\theta) := \mathbf{1}[\text{Node } i \text{ is isolated in } \mathbb{K}_n(\theta)], \quad i = 1, \dots, n$$

The number of isolated nodes in $\mathbb{K}_n(\theta)$ is simply given by

$$I_n(\theta) := \sum_{i=1}^n \chi_{n,i}(\theta).$$

The random graph $\mathbb{K}_n(\theta)$ has no isolated nodes if $I_n(\theta) = 0$, in which case

$$P(n; \theta) = \mathbb{P}[I_n(\theta) = 0]. \quad (21)$$

Let $\Pi(\mu)$ denote a Poisson rv with parameter μ . Using the Stein-Chen method we obtain a Poisson approximation result which yields convergence to a Poisson rv.

Theorem 4.4: *Consider an admissible pair of functions $P, K : \mathbb{N}_0 \rightarrow \mathbb{N}$ whose function $\alpha : \mathbb{N}_0 \rightarrow \mathbb{R}$ determined through (16) satisfies*

$$\lim_{n \rightarrow \infty} \alpha_n = \gamma \quad (22)$$

for some scalar γ . Then, we have the convergence

$$I_n(\theta_n) \Rightarrow_n \Pi(e^{-\gamma}) \quad (23)$$

with \Rightarrow_n denoting convergence in distribution (with n going to infinity).

The attending “double exponential” result is now immediate from (21), and takes the form

$$\lim_{n \rightarrow \infty} P(n; \theta_n) = e^{-e^{-\gamma}} \quad (24)$$

for any admissible pair of functions $P, K : \mathbb{N}_0 \rightarrow \mathbb{N}$ satisfying the assumptions of Theorem 4.4. This result readily implies Theorem 4.1 by an easy monotonicity argument.

Finally, the conjectured asymptotic equivalence of graph connectivity and absence of isolated nodes, which underlies Conjecture 4.3, now leads to the desired “double exponential” result, namely

$$\lim_{n \rightarrow \infty} P^*(n; \theta_n) = e^{-e^{-\gamma}}$$

under the assumptions required for (24) to hold.

V. A PROOF OF THEOREM 4.1

Fix $n = 2, 3, \dots$ and consider $\theta = (P, K)$ with positive integers K and P such that $K < P$. The equivalence (21) provides the basis for proving Theorem 4.1 by means of the method of first and second moments [11, p. 55]. This approach relies on the well-known bounds

$$1 - \mathbb{E}[I_n(\theta)] \leq \mathbb{P}[I_n(\theta) = 0] \quad (25)$$

and

$$\mathbb{P}[I_n(\theta) = 0] \leq 1 - \frac{\mathbb{E}[I_n(\theta)^2]}{\mathbb{E}[I_n(\theta)]^2}. \quad (26)$$

We proceed by evaluating these bounds: The rvs $\chi_{n,1}(\theta), \dots, \chi_{n,n}(\theta)$ being exchangeable, we find

$$\mathbb{E}[I_n(\theta)] = n\mathbb{E}[\chi_{n,1}(\theta)] \quad (27)$$

and

$$\begin{aligned} \mathbb{E}[I_n(\theta)^2] &= n\mathbb{E}[\chi_{n,1}(\theta)] \\ &\quad + n(n-1)\mathbb{E}[\chi_{n,1}(\theta)\chi_{n,2}(\theta)] \end{aligned} \quad (28)$$

by the binary nature of the rvs involved. It then follows that

$$\begin{aligned} &\frac{\mathbb{E}[I_n(\theta)^2]}{\mathbb{E}[I_n(\theta)]^2} \\ &= \frac{n\mathbb{E}[\chi_{n,1}(\theta)]}{(n\mathbb{E}[\chi_{n,1}(\theta)])^2} + \frac{n(n-1)\mathbb{E}[\chi_{n,1}(\theta)\chi_{n,2}(\theta)]}{(n\mathbb{E}[\chi_{n,1}(\theta)])^2} \\ &= \frac{1}{\mathbb{E}[I_n(\theta)]} + \frac{n-1}{n} \cdot \frac{\mathbb{E}[\chi_{n,1}(\theta)\chi_{n,2}(\theta)]}{(\mathbb{E}[\chi_{n,1}(\theta)])^2}. \end{aligned} \quad (29)$$

The proof of Theorem 4.1 passes through the next two technical lemmas which are established in Sections VII and VIII, respectively.

Lemma 5.1: *For any pair of functions $P, K : \mathbb{N}_0 \rightarrow \mathbb{N}$, it holds that*

$$\lim_{n \rightarrow \infty} \mathbb{E}[I_n(\theta_n)] = \begin{cases} 0 & \text{if } \lim_{n \rightarrow \infty} \alpha_n = +\infty \\ \infty & \text{if } \lim_{n \rightarrow \infty} \alpha_n = -\infty \end{cases} \quad (30)$$

where the function $\alpha : \mathbb{N}_0 \rightarrow \mathbb{R}$ is determined through (16).

Lemma 5.2: *For any pair of functions $P, K : \mathbb{N}_0 \rightarrow \mathbb{N}$, it holds that*

$$\lim_{n \rightarrow \infty} \frac{\mathbb{E}[\chi_{n,1}(\theta_n)\chi_{n,2}(\theta_n)]}{(\mathbb{E}[\chi_{n,1}(\theta_n)])^2} = 1 \quad (31)$$

whenever the function $\alpha : \mathbb{N}_0 \rightarrow \mathbb{R}$ determined through (16) satisfies the condition

$$\lim_{n \rightarrow \infty} \alpha_n = -\infty. \quad (32)$$

To complete the proof of Theorem 4.1, pick a pair of functions $P, K : \mathbb{N}_0 \rightarrow \mathbb{N}$ with function $\alpha : \mathbb{N}_0 \rightarrow \mathbb{R}$ determined through (16). For each $n = 1, 2, \dots$, we conclude from (25) and (26) that

$$1 - \mathbb{E}[I_n(\theta_n)] \leq \mathbb{P}[I_n(\theta_n) = 0] \quad (33)$$

and

$$\mathbb{P}[I_n(\theta_n) = 0] \leq 1 - \frac{\mathbb{E}[I_n(\theta_n)^2]}{\mathbb{E}[I_n(\theta_n)]^2}. \quad (34)$$

Letting n go to infinity in (33) under the assumption $\lim_{n \rightarrow \infty} \alpha_n = \infty$, we get $\lim_{n \rightarrow \infty} P(n; \theta_n) = 1$ from Lemma 5.1.

Next, let n go to infinity in (34) under the condition (32): Lemma 5.1 already yields $\lim_{n \rightarrow \infty} \mathbb{E}[I_n(\theta_n)] = \infty$, while Lemma 5.2 leads (via (29)) to

$$\lim_{n \rightarrow \infty} \frac{\mathbb{E}[I_n(\theta_n)^2]}{\mathbb{E}[I_n(\theta_n)]^2} = 1.$$

The conclusion $\lim_{n \rightarrow \infty} P(n; \theta_n) = 0$ is now immediate. This completes the proof of Theorem 4.1. \blacksquare

VI. SOME EASY PRELIMINARIES

In this section we have collected for easy reference several technical facts that will be used repeatedly in the discussion.

A. A useful decomposition

With $0 \leq x < 1$, it is a simple matter to check that

$$\log(1-x) = - \int_0^x \frac{1}{1-t} dt = -x - \Psi(x) \quad (35)$$

where we have set

$$\Psi(x) := \int_0^x \frac{t}{1-t} dt, \quad 0 \leq x < 1.$$

L'Hospital's rule yields

$$\lim_{x \downarrow 0} \frac{\Psi(x)}{x^2} = \frac{1}{2}, \quad (36)$$

while the decomposition (35) and the non-negativity of Ψ lead to the standard bound

$$1-x \leq e^{-x}, \quad x \in [0, 1]. \quad (37)$$

B. Simple consequences of the condition (32)

Pick a pair of functions $P, K : \mathbb{N}_0 \rightarrow \mathbb{N}$ with function $\alpha : \mathbb{N}_0 \rightarrow \mathbb{R}$ determined through (16). Under condition (32), we have $\alpha_n < 0$ for n sufficiently large, in which case $\alpha_n = -|\alpha_n|$. By non-negativity, $|\alpha_n| \leq \log n$ on that range and the inequality

$$\frac{K_n^2}{P_n} \leq \frac{\log n}{n} \quad (38)$$

follows, whence

$$\frac{K_n}{P_n} \leq \sqrt{\frac{1}{P_n} \cdot \frac{\log n}{n}} \leq \sqrt{\frac{\log n}{n}}. \quad (39)$$

As a result, we see that

$$\lim_{n \rightarrow \infty} \frac{K_n}{P_n} = 0 \quad (40)$$

and

$$\lim_{n \rightarrow \infty} \frac{K_n}{P_n - cK_n} = 0, \quad c \geq 0. \quad (41)$$

By virtue of (40), we note that for each $c > 0$, we have $P_n > cK_n$ for all n sufficiently large.

Next, for n sufficiently large, the first inequality in (39) gives

$$\begin{aligned} n \frac{K_n^3}{P_n^2} &\leq \frac{n}{P_n^2} \cdot \left(\sqrt{\frac{\log n}{n}} P_n \right)^3 \\ &= n \left(\sqrt{\frac{\log n}{n}} \right)^3 \cdot \frac{\sqrt{P_n^3}}{P_n^2} \\ &\leq \sqrt{\frac{(\log n)^3}{n}}, \end{aligned}$$

and the conclusion

$$\lim_{n \rightarrow \infty} n \frac{K_n^3}{P_n^2} = 0 \quad (42)$$

is now immediate.

C. An easy technical fact

The next technical fact will help simplify the discussion in a number of places.

Lemma 6.1: Consider an pair of functions $P, K : \mathbb{N}_0 \rightarrow \mathbb{N}$ such that the function $\alpha : \mathbb{N}_0 \rightarrow \mathbb{R}$ determined through (16) satisfies the condition (32). Then for any $c \geq 0$, we have

$$\lim_{n \rightarrow \infty} n K_n \Psi \left(\frac{K_n}{P_n - cK_n} \right) = 0 \quad (43)$$

and

$$\lim_{n \rightarrow \infty} \left(1 - \frac{K_n}{P_n - cK_n} \right)^{K_n} = 1. \quad (44)$$

Proof. Fix $c \geq 0$ and recall (36) and (41). For each $n = 1, 2, \dots$ sufficiently large, we can write

$$\begin{aligned} &K_n \Psi \left(\frac{K_n}{P_n - cK_n} \right) \\ &= K_n \left(\frac{K_n}{P_n - cK_n} \right)^2 \cdot \left(\frac{\Psi \left(\frac{K_n}{P_n - cK_n} \right)}{\left(\frac{K_n}{P_n - cK_n} \right)^2} \right) \\ &= K_n \left(\frac{K_n}{P_n - cK_n} \right)^2 \cdot \frac{1}{2} (1 + o(1)) \end{aligned}$$

with

$$\begin{aligned} \frac{K_n}{P_n - cK_n} &= \frac{K_n}{P_n} \cdot \left(1 - c \frac{K_n}{P_n} \right)^{-1} \\ &= \frac{K_n}{P_n} (1 + o(1)). \end{aligned}$$

Collecting these facts leads to

$$nK_n\Psi\left(\frac{K_n}{P_n - cK_n}\right) = \frac{nK_n^3}{2P_n^2}(1 + o(1))$$

and (42) readily implies (43).

To establish (44), we need only show that

$$\lim_{n \rightarrow \infty} K_n \log\left(1 - \frac{K_n}{P_n - cK_n}\right) = 0. \quad (45)$$

For each $n = 2, 3, \dots$, we rely on the decomposition (35) to write

$$\begin{aligned} & K_n \log\left(1 - \frac{K_n}{P_n - cK_n}\right) \\ &= -K_n \left(\frac{K_n}{P_n - cK_n} + \Psi\left(\frac{K_n}{P_n - cK_n}\right) \right) \\ &= -\frac{K_n^2}{P_n - cK_n} - K_n \Psi\left(\frac{K_n}{P_n - cK_n}\right). \end{aligned} \quad (46)$$

The arguments given in the first part of the proof also show that

$$K_n \Psi\left(\frac{K_n}{P_n - cK_n}\right) = \frac{K_n^3}{2P_n^2}(1 + o(1)) \quad (47)$$

and

$$\begin{aligned} \frac{K_n^2}{P_n - cK_n} &= \frac{K_n^2}{P_n} \left(1 - \frac{K_n}{P_n}\right)^{-1} \\ &= \frac{K_n^2}{P_n} (1 + o(1)). \end{aligned} \quad (48)$$

Let n go to infinity in (46): Making use of (47) and (48) we readily get (44) from the limits (38) and (42). ■

D. Factorials and bounds

For positive integers K and P such that $2K < P$, we have

$$\begin{aligned} \frac{\binom{P-K}{K}}{\binom{P}{K}} &= \frac{(P-K)!}{P!} \cdot \frac{(P-K)!}{(P-2K)!} \\ &= \frac{(P-K)(P-K-1)\dots(P-2K+1)}{P(P-1)\dots(P-K+1)} \\ &= \prod_{\ell=0}^{K-1} \left(1 - \frac{K}{P-\ell}\right). \end{aligned} \quad (49)$$

The bounds

$$\left(1 - \frac{K}{P-K}\right)^K \leq \frac{\binom{P-K}{K}}{\binom{P}{K}} \leq \left(1 - \frac{K}{P}\right)^K \quad (50)$$

are now immediate from the inequalities $P-K < P-\ell \leq P$, $\ell = 0, \dots, K-1$.

VII. A PROOF OF LEMMA 5.1

Consider $\theta = (P, K)$ with positive integers K and P such that $2K < P$ and fix $n = 2, 3, \dots$. Under the enforced independence assumptions, it is a simple matter to see that

$$\mathbb{E}[\chi_{n,i}(\theta)] = q(\theta)^{n-1} \quad (51)$$

for all $i = 1, \dots, n$, whence

$$\mathbb{E}[I_n(\theta)] = nq(\theta)^{n-1}. \quad (52)$$

Next substitute in this expression θ by θ_n by means of an admissible pair of functions $P, K : \mathbb{N}_0 \rightarrow \mathbb{N}$. First we deal with the case $\lim_{n \rightarrow \infty} \alpha_n = \infty$: From (50) we obtain

$$nq(\theta_n)^{n-1} \leq e^{\alpha'_n}$$

for all $n = 1, 2, \dots$ with

$$\begin{aligned} \alpha'_n &:= \log n - (n-1) \frac{K_n^2}{P_n} \\ &= \log n - \frac{(n-1)}{n} \cdot (\log n + \alpha_n) \\ &= \frac{\log n}{n} - \frac{n-1}{n} \alpha_n. \end{aligned}$$

We have $\lim_{n \rightarrow \infty} \alpha'_n = -\infty$ whenever $\lim_{n \rightarrow \infty} \alpha_n = \infty$, whence $\lim_{n \rightarrow \infty} nq(\theta_n)^{n-1} = 0$. The conclusion $\lim_{n \rightarrow \infty} \mathbb{E}[I_n(\theta_n)] = 0$ is now reached upon invoking (52). ■

In the case $\lim_{n \rightarrow \infty} \alpha_n = -\infty$ we note that the bounds (50) yield

$$n \left(1 - \frac{K_n}{P_n - K_n}\right)^{nK_n} \leq nq(\theta)^{n-1} \quad (53)$$

for all $n = 1, 2, \dots$. We find it convenient to write the left handside of this last inequality as

$$n \left(1 - \frac{K_n}{P_n - K_n}\right)^{nK_n} = e^{\alpha''_n} \quad (54)$$

where

$$\begin{aligned} \alpha''_n &= \log n + nK_n \log\left(1 - \frac{K_n}{P_n - K_n}\right) \\ &= \log n - nK_n \left(\frac{K_n}{P_n - K_n} + \Psi\left(\frac{K_n}{P_n - K_n}\right) \right) \\ &= \log n - n \frac{K_n^2}{P_n - K_n} - nK_n \Psi\left(\frac{K_n}{P_n - K_n}\right) \end{aligned} \quad (55)$$

as we use the decomposition (35) in the second equality. The first two terms in (55) combine as

$$\begin{aligned} & \log n - n \frac{K_n^2}{P_n - K_n} \\ &= \log n - n \frac{K_n^2}{P_n} \cdot \left(1 + \left(\frac{P_n}{P_n - K_n} - 1\right)\right) \\ &= \left(\log n - n \frac{K_n^2}{P_n}\right) - n \frac{K_n^2}{P_n} \cdot \frac{K_n}{P_n - K_n} \\ &= -\alpha_n - n \frac{K_n^2}{P_n} \cdot \frac{K_n}{P_n - K_n}. \end{aligned}$$

Next, from (40) we observe that

$$\begin{aligned} n \frac{K_n^2}{P_n} \frac{K_n}{P_n - K_n} &= n \frac{K_n^3}{P_n^2} \left(1 - \frac{K_n}{P_n}\right)^{-1} \\ &= n \frac{K_n^3}{P_n^2} (1 + o(1)). \end{aligned}$$

Therefore, under the condition $\lim_{n \rightarrow \infty} \alpha_n = -\infty$, we get

$$\lim_{n \rightarrow \infty} n \frac{K_n^2}{P_n} \frac{K_n}{P_n - K_n} = 0$$

by virtue of (41) (with $c = 1$) and (42). We can then conclude to

$$\lim_{n \rightarrow \infty} \left(\log n - n \frac{K_n^2}{P_n - K_n} \right) = \infty, \quad (56)$$

and applying Lemma 6.1 (with $c = 1$) to the last term in (55) we find

$$\lim_{n \rightarrow \infty} n K_n \Psi \left(\frac{K_n}{P_n - K_n} \right) = 0. \quad (57)$$

Letting n go to infinity in (55), we conclude from (56) and (57) that $\lim_{n \rightarrow \infty} \alpha_n'' = -\lim_{n \rightarrow \infty} \alpha_n = \infty$ since $\lim_{n \rightarrow \infty} \alpha_n = -\infty$. It is now plain from (53) and (54) that $\lim_{n \rightarrow \infty} \mathbb{E}[I_n(\theta_n)] = \infty$ by virtue of (52). ■

VIII. A PROOF OF LEMMA 5.2

Consider $\theta = (P, K)$ with positive integers K and P such that $3K < P$, and write

$$b(\theta) := \frac{\binom{P-2K}{K}}{\binom{P}{K}}.$$

Fix $n = 2, 3, \dots$. Under the enforced independence assumptions, it is a simple matter to check that

$$\mathbb{E}[\chi_{n,i}(\theta)\chi_{n,j}(\theta)] = q(\theta)b(\theta)^{n-2}$$

for distinct $i, j = 1, \dots, n$, whence

$$\frac{\mathbb{E}[\chi_{n,1}(\theta)\chi_{n,2}(\theta)]}{(\mathbb{E}[\chi_{n,1}(\theta)])^2} = \frac{q(\theta)b(\theta)^{n-2}}{q(\theta)^{2(n-1)}} = \frac{b(\theta)^{n-2}}{q(\theta)^{2n-3}}. \quad (58)$$

On the way to evaluating this ratio, we note that

$$\begin{aligned} \frac{b(\theta)^{n-2}}{q(\theta)^{2n-3}} &= \left(\frac{\binom{P-2K}{K}}{\binom{P}{K}} \right)^{n-2} \cdot \left(\frac{\binom{P}{K}}{\binom{P-K}{K}} \right)^{2n-3} \\ &= \left(\frac{\binom{P-2K}{K}}{\binom{P-K}{K}} \right)^{n-2} \cdot \left(\frac{\binom{P}{K}}{\binom{P-K}{K}} \right)^{n-1} \\ &= \frac{r(\theta)^{n-2}}{q(\theta)} \end{aligned} \quad (59)$$

where we have used the notation

$$r(\theta) := \frac{\binom{P-2K}{K}}{\binom{P-K}{K}} \cdot \frac{\binom{P}{K}}{\binom{P-K}{K}}.$$

Under the condition (32) we show below that

$$\lim_{n \rightarrow \infty} q(\theta_n) = 1 \quad (60)$$

and

$$\lim_{n \rightarrow \infty} r(\theta_n)^{n-2} = 1. \quad (61)$$

Once this is done, it is plain from (59) that

$$\lim_{n \rightarrow \infty} \frac{b(\theta_n)^{n-2}}{q(\theta_n)^{2n-3}} = 1 \quad (62)$$

and the desired result (31) follows from (58).

In order to establish (60) and (61) we proceed as in the proof of Lemma 5.1: First, making use of (50) we obtain

$$\left(1 - \frac{K_n}{P_n - K_n} \right)^{K_n} \leq q(\theta_n) \leq \left(1 - \frac{K_n}{P_n} \right)^{K_n} \quad (63)$$

for all $n = 2, 3, \dots$. Letting n go to infinity and making use of (44) (with $c = 0$ and $c = 1$) we get (60).

Next, using (50), this time with P_n replaced by $P_n - K_n$, we get

$$\left(1 - \frac{K_n}{P_n - 2K_n} \right)^{K_n} \leq \frac{\binom{P_n - 2K_n}{K_n}}{\binom{P_n - K_n}{K_n}} \leq \left(1 - \frac{K_n}{P_n - K_n} \right)^{K_n} \quad (64)$$

for all $n = 2, 3, \dots$. Combining (63) and (64) readily gives

$$\left(\frac{1 - \frac{K_n}{P_n - 2K_n}}{1 - \frac{K_n}{P_n}} \right)^{K_n} \leq r(\theta_n) \leq 1. \quad (65)$$

It is now plain that the convergence (61) will be established if we can show that

$$\lim_{n \rightarrow \infty} (n-2)K_n \log \left(\frac{1 - \frac{K_n}{P_n - 2K_n}}{1 - \frac{K_n}{P_n}} \right) = 0. \quad (66)$$

To that end, for each $n = 2, 3, \dots$ we note that

$$\begin{aligned} &(n-2)K_n \cdot \log \left(\frac{1 - \frac{K_n}{P_n - 2K_n}}{1 - \frac{K_n}{P_n}} \right) \\ &= -(n-2)K_n \cdot \left(\frac{K_n}{P_n - 2K_n} + \Psi \left(\frac{K_n}{P_n - 2K_n} \right) \right) \\ &\quad + (n-2)K_n \cdot \left(\frac{K_n}{P_n} + \Psi \left(\frac{K_n}{P_n} \right) \right) \\ &= -\frac{2(n-2)K_n^3}{P_n(P_n - 2K_n)} \\ &\quad - (n-2)K_n \cdot \left(\Psi \left(\frac{K_n}{P_n - 2K_n} \right) - \Psi \left(\frac{K_n}{P_n} \right) \right) \\ &= -\frac{2(n-2)K_n^3}{P_n^2} \cdot \left(1 - \frac{2K_n}{P_n} \right)^{-1} \\ &\quad - (n-2)K_n \cdot \left(\Psi \left(\frac{K_n}{P_n - 2K_n} \right) - \Psi \left(\frac{K_n}{P_n} \right) \right). \end{aligned}$$

Applying Lemma 6.1 (with $c = 0$ and $c = 2$) yields

$$\lim_{n \rightarrow \infty} (n-2)K_n \cdot \left(\Psi \left(\frac{K_n}{P_n - 2K_n} \right) - \Psi \left(\frac{K_n}{P_n} \right) \right) = 0,$$

while (41) (with $c = 2$) and (42) together lead to

$$\lim_{n \rightarrow \infty} \frac{(n-2)K_n^3}{P_n^2} \left(1 - \frac{2K_n}{P_n} \right)^{-1} = 0.$$

The convergence (66) now follows. ■

IX. CALCULATIONS

The proof of Theorem 4.4 will make use of the calculations presented in this section:

Lemma 9.1: Consider an admissible pair of functions $P, K : \mathbb{N}_0 \rightarrow \mathbb{N}$ whose function $\alpha : \mathbb{N}_0 \rightarrow \mathbb{R}$ satisfies (22) for some scalar γ . Then for arbitrary $c \geq 0$, we have

$$\lim_{n \rightarrow \infty} n \left(1 - \frac{K_n}{P_n - cK_n} \right)^{(n-1)K_n} = e^{-\gamma}. \quad (67)$$

Under the assumptions of Lemma 9.1 we note the following: Pick $\varepsilon > 0$. Adapting the arguments of Section VI-B, we get

$$\frac{K_n^2}{P_n} \leq \frac{\log n + |\gamma| + \varepsilon}{n} \quad (68)$$

for n sufficiently large, whence

$$\frac{K_n}{P_n} \leq \sqrt{\frac{\log n + |\gamma| + \varepsilon}{n}} \leq \sqrt{2 \frac{\log n}{n}} \quad (69)$$

eventually.

Proof. Fix $n = 1, 2, 3, \dots$ and $c = 0, 1$. The decomposition (35) gives

$$\begin{aligned} & (n-1)K_n \log \left(1 - \frac{K_n}{P_n - cK_n} \right) \\ &= -(n-1) \frac{K_n^2}{P_n - cK_n} - (n-1)K_n \Psi \left(\frac{K_n}{P_n - cK_n} \right). \end{aligned}$$

Thus,

$$n \left(1 - \frac{K_n}{P_n - cK_n} \right)^{(n-1)K_n} = e^{A_n} e^{B_n} \quad (70)$$

where

$$A_n := \log n - (n-1) \frac{K_n^2}{P_n - cK_n}$$

and

$$B_n := -(n-1)K_n \Psi \left(\frac{K_n}{P_n - cK_n} \right).$$

We now inspect each term in turn: First,

$$\begin{aligned} A_n &= \log n - (n-1) \frac{K_n^2}{P_n} \cdot \left(1 - c \frac{K_n}{P_n} \right)^{-1} \\ &= \log n - \frac{n-1}{n} \cdot (\log n + \alpha_n) \cdot \left(1 - c \frac{K_n}{P_n} \right)^{-1} \\ &= \frac{\log n \cdot \left(1 - c \frac{K_n}{P_n} \right) - \frac{n-1}{n} \cdot (\log n + \alpha_n)}{\left(1 - c \frac{K_n}{P_n} \right)} \\ &= \frac{\log n \cdot \left(\frac{1}{n} - c \frac{K_n}{P_n} \right) - \frac{n-1}{n} \alpha_n}{\left(1 - c \frac{K_n}{P_n} \right)} \\ &= \frac{\left(\frac{\log n}{n} - c \log n \cdot \frac{K_n}{P_n} \right) - \frac{n-1}{n} \alpha_n}{\left(1 - c \frac{K_n}{P_n} \right)}. \end{aligned} \quad (71)$$

It is plain from (69) that

$$\lim_{n \rightarrow \infty} \frac{K_n}{P_n} = \lim_{n \rightarrow \infty} \log n \cdot \left(\frac{K_n}{P_n} \right) = 0, \quad (72)$$

and we conclude that

$$\lim_{n \rightarrow \infty} A_n = -\gamma. \quad (73)$$

Next, we deal with the second factor in (70): For each $n = 1, 2, \dots$, we have

$$\begin{aligned} B_n &= -(n-1)K_n \Psi \left(\frac{K_n}{P_n - cK_n} \right) \\ &= -(n-1)K_n \Psi \left(\frac{\frac{K_n}{P_n}}{1 - c \frac{K_n}{P_n}} \right) \\ &= -(n-1) \frac{\frac{K_n^3}{P_n^2}}{\left(1 - c \frac{K_n}{P_n} \right)^2} \cdot \frac{\Psi \left(\frac{\frac{K_n}{P_n}}{1 - c \frac{K_n}{P_n}} \right)}{\left(\frac{\frac{K_n}{P_n}}{1 - c \frac{K_n}{P_n}} \right)^2} \\ &= -(n-1) \frac{K_n^3}{2P_n^2} (1 + o(1)) \end{aligned} \quad (74)$$

by virtue of (36) and (69). Therefore, using (68) and (69) we find

$$\lim_{n \rightarrow \infty} \frac{K_n^3}{P_n^2} = \lim_{n \rightarrow \infty} \frac{K_n^2}{P_n} \cdot \lim_{n \rightarrow \infty} \frac{K_n}{P_n^2} = 0 \quad (75)$$

and it is now immediate that

$$\lim_{n \rightarrow \infty} B_n = 0. \quad (76)$$

Finally, let n go to infinity in (70). We get (67) upon collecting (73) and (76). \blacksquare

Lemma 9.1 has the following useful consequences: For each $n = 1, 2, \dots$, we get

$$\begin{aligned} \frac{K_n^2}{P_n - K_n} &= \frac{K_n^2}{P_n} \cdot \frac{P_n}{P_n - K_n} \\ &= \frac{\log n + \beta_n}{n} \end{aligned} \quad (77)$$

for some function $\beta : \mathbb{N}_0 \rightarrow \mathbb{R}$ given by

$$\beta_n := \frac{\alpha_n + \frac{K_n}{P_n} \log n}{1 - \frac{K_n}{P_n}}, \quad n = 1, 2, \dots$$

Invoking (72) and (75) we get that $\lim_{n \rightarrow \infty} \beta_n = \gamma$ since $\lim_{n \rightarrow \infty} \alpha_n = \gamma$. Applying Lemma 9.1 (with P_n replaced by $P_n - K_n$) readily leads to the conclusion

X. A PROOF OF THEOREM 4.4

By a coupling argument the rvs $\chi_{n,1}(\theta), \dots, \chi_{n,n}(\theta)$ can be shown to be *negatively related* (in the technical sense given in [1, p. Defn. 2.1.1, p. 24]). As a result, the basic Stein-Chen inequality [1, Cor. 2.C.2, p. 26] takes on the simpler form

$$d_{TV}(I_n(\theta); \Pi(\mathbb{E}[I_n(\theta)])) \leq \frac{\mathbb{E}[I_n(\theta)] - \text{Var}[I_n(\theta)]}{\mathbb{E}[I_n(\theta)]} \quad (78)$$

where d_{TV} denotes the total variation distance. The triangular inequality for the total variation distance yields

$$\begin{aligned} d_{TV}(I_n(\theta); \Pi(e^{-\gamma})) &\leq d_{TV}(I_n(\theta); \Pi(\mathbb{E}[I_n(\theta)])) \\ &\quad + d_{TV}(\Pi(\mathbb{E}[I_n(\theta)]); \Pi(e^{-\gamma})) \end{aligned} \quad (79)$$

We study each of the terms in turn.

First, the estimate

$$d_{TV}(\Pi(\mathbb{E}[I_n(\theta)]); \Pi(e^{-\gamma})) \leq |\mathbb{E}[I_n(\theta)] - e^{-\gamma}| \quad (80)$$

is well known [13, p. 58]. Next, direct substitution from (27) and (28) gives

$$\begin{aligned} & \mathbb{E}[I_n(\theta)] - \text{Var}[I_n(\theta)] \\ &= \mathbb{E}[I_n(\theta)] - \left(\mathbb{E}[I_n(\theta)^2] - \mathbb{E}[I_n(\theta)]^2 \right) \\ &= (n\mathbb{E}[\chi_{n,1}(\theta)])^2 - n(n-1)\mathbb{E}[\chi_{n,1}(\theta)\chi_{n,2}(\theta)] \end{aligned}$$

whence

$$\begin{aligned} & \frac{\mathbb{E}[I_n(\theta)] - \text{Var}[I_n(\theta)]}{\mathbb{E}[I_n(\theta)]} \\ &= n\mathbb{E}[\chi_{n,1}(\theta)] - (n-1) \frac{\mathbb{E}[\chi_{n,1}(\theta)\chi_{n,2}(\theta)]}{\mathbb{E}[\chi_{n,1}(\theta)]} \\ &= n \left(\frac{\binom{P-K}{K}}{\binom{P}{K}} \right)^{n-1} - (n-1) \left(\frac{\binom{P-2K}{K}}{\binom{P-K}{K}} \right)^{n-2} \end{aligned}$$

upon making use of the expressions (51) and (58).

Finally, substitute θ by θ_n by means of an admissible pair of functions $P, K : \mathbb{N}_0 \rightarrow \mathbb{N}$ whose function $\alpha : \mathbb{N}_0 \rightarrow \mathbb{R}$ satisfies (22) for some scalar γ : In view of (50) and (52) we get

$$\lim_{n \rightarrow \infty} \mathbb{E}[I_n(\theta_n)] = \lim_{n \rightarrow \infty} n \left(\frac{\binom{P_n - K_n}{K_n}}{\binom{P_n}{K_n}} \right)^{n-1} = e^{-\gamma} \quad (81)$$

by making use of Lemma 9.1. Next, with the help of (64), we also conclude from Lemma 9.1 that

$$\lim_{n \rightarrow \infty} n \left(\frac{\binom{P_n - 2K_n}{K_n}}{\binom{P_n - K_n}{K_n}} \right)^{n-1} = e^{-\gamma}, \quad (82)$$

whence

$$\lim_{n \rightarrow \infty} \frac{\binom{P_n - 2K_n}{K_n}}{\binom{P_n - K_n}{K_n}} = 1 \quad (83)$$

upon noting that

$$\lim_{n \rightarrow \infty} \left(\frac{e^{-\gamma}}{n} \right)^{\frac{1}{n-1}} = 1.$$

It is now a simple matter to see that

$$\lim_{n \rightarrow \infty} (n-1) \left(\frac{\binom{P_n - 2K_n}{K_n}}{\binom{P_n - K_n}{K_n}} \right)^{n-2} = e^{-\gamma}, \quad (84)$$

Collecting (81) and (84) we find

$$\lim_{n \rightarrow \infty} \frac{\mathbb{E}[I_n(\theta_n)] - \text{Var}[I_n(\theta_n)]}{\mathbb{E}[I_n(\theta_n)]} = 0. \quad (85)$$

Combining (81) and (85) with (78), (79) and (80) conclude that

$$\lim_{n \rightarrow \infty} d_{TV}(I_n(\theta_n); \Pi(e^{-\gamma})) = 0,$$

or equivalently,

$$I_n(\theta_n) \Rightarrow_n \Pi(e^{-\gamma}).$$
