ABSTRACT

This paper considers the Poisson equation associated with time-homogeneous Markov chains on a countable state space. The discussion emphasizes probabilistic arguments and focuses on three separate issues, namely (i) the existence and uniqueness of solutions to the Poisson equation, (ii) growth estimates and bounds on these solutions and (iii) their parametric dependence. Answers to these questions are obtained under a variety of recurrence conditions.

Motivating applications can be found in the theory of Markov decision processes in both its adaptive and non-adaptive formulations, and in the theory of Stochastic Approximations. The results complement available results from Potential Theory for Markov chains, and are therefore of independent interest.

Keywords: Markov Chains, Poisson Equation, smoothness of solutions.

1. INTRODUCTION

Let $P = (p_{xy})$ be the one-step transition matrix for a time-homogeneous Markov chain $\{X_t, \ t = 0, 1, \ldots\}$ taking values in some countable space $S$. This paper is devoted to the corresponding Poisson equation with forcing function $c : S \to \mathbb{R}$, namely

$$h(x) + J = c(x) + \sum_y p_{xy} h(y), \quad x \in S$$

(1.1)

for scalar $J$ and mapping $h : S \to \mathbb{R}$. This equation arises naturally in a variety of problems associated with Markov chains as the following examples indicate.

1. As shown in Section 3, solving the Poisson equation provides a means to evaluate the long-run average cost $J$ associated with the cost function $c$ [26]: If (1.1) has a solution $(h, J)$ and some mild growth conditions are satisfied, then Lemma 3.1 states that

$$J = \lim_t \mathbb{E}_\mu \left[ \frac{1}{t+1} \sum_{s=0}^{t} c(X_s) \right]$$

(1.2)

where $\mu$ is the initial distribution and $\mathbb{E}_\mu$ is the corresponding expectation operator.

2. In recent years, there has been widespread interest in stochastic approximation algorithms as a means to solve increasingly complex engineering problems [1,12]. As a result, focus has shifted from the original Robbins-Monro algorithm to (projected) stochastic approximations driven by Markovian "noise" or "state" processes. Properties of solutions to an appropriate Poisson equation play an essential role when establishing the a.s. convergence of such adaptive algorithms [1,13,17,19,20,29].

3. In the context of Markov decision processes (MDPs), the need for adaptive policies can arise in response to both modeling uncertainties and computational limitations [30]. Several adaptive policies have been proposed as "implementations" to a Markov stationary policy, and shown to yield the same cost performance [3, 13, 14,18,30]. Here too, the analysis requires precise information on the solution to the Poisson equation associated with the non-adaptive policy [30].

In many of these applications, it is appropriate to view the forcing function $c$ and the transition matrix $P$ as parametrized, say by some parameter $\theta$ (which may be loosely interpreted as a control variable). The analysis then typically exploits smoothness properties (in $\theta$) of the solution $h$ together with various growth estimates (in $x$) for $h$. In addition, estimates on the moments of $\{h(X_t), \ t = 0, 1, 2, \ldots\}$ are required, with the added difficulty that the resulting process $\{X_t, \ t =$
0, 1, 2, . . .} is not necessarily Markovian (say, under the given stochastic approximation scheme or adaptive policy).

In this paper, our main objective is to develop methods for addressing the concerns above in a systematic fashion. We emphasize a probabilistic viewpoint, whenever possible, and focus mostly on the following three sets of issues, namely

1. Existence and uniqueness of solutions to the Poisson equation (1.1);
2. Growth estimates and bounds on these solutions; and
3. Conditions for smoothness in the parameter of these solutions when dealing with the parametric case as would arise in establishing the a.s. convergence of stochastic approximations.

Answers to these questions are given under a variety of recurrence conditions. As we try to keep the exposition relatively self-contained, we have included some standard material on the Poisson equation. In addition to its tutorial merit, the discussion given here provides a unified treatment to many of the issues associated with the Poisson equation, e.g., existence, uniqueness and representation of solutions. This is achieved by manipulating a single martingale naturally induced by the Poisson equation.

Questions of existence and uniqueness of solutions to (1.1) have obvious and natural points of contact with the Potential Theory for Markov chains [11,23]. However, it is unfortunate that many situations of interest in applications, say in the context of MDPs, are not readily covered by classical Potential Theory. Indeed, the classical theory treats the purely transient and recurrent cases separately, and provides drastically different results for each situation. This approach is thus of limited use in the above-mentioned situations, where the recurrence structure of the Markov chain is typically far more complex in that it combines both transient and recurrent states. Here, in contrast with the analytical approach of classical Potential Theory, emphasis has been put on giving an explicit representation of the solution to (1.1) with a clear probabilistic interpretation.

This probabilistic approach allows for a relatively elementary treatment of existence and uniqueness, under a rather general recurrence structure. Results are obtained in various degrees of completeness for both finite and countably infinite state spaces; recurrence structures include multiple positive recurrent classes, and transient classes. A representation for \( h \) is derived in detail in the case of a single positive recurrent class under integrability conditions involving the forcing function \( c \). The derivation uses elementary methods, and provides intuition into more general situations. This representation is also shown to hold in the multiple class countable case, and readily
lends itself to establishing natural bounds on the growth rate of \( h \) (as a function of the state), and to investigating smoothness properties in the parametrized problem.

The paper is organized as follows: The set-up is given in Section 2, together with the basic martingale associated with (1.1). Various uniqueness results on the solution \((J, h)\) are discussed in Section 3. We give two decomposition results in Section 4; one such decomposition is based on the decomposition of the state space \( S \) into its recurrent and transient classes, while the other is an analog of the standard Green decomposition and relies on an expansion of the forcing function in terms of more "elementary" forcing functions. To set the stage for the countably infinite case, we briefly recall an algebraic treatment of the finite-state case in Section 5. In section 6 an explicit representation for the solution is developed in terms of some recurrence times, under a single positive recurrent class assumption. An example is developed in Section 7 to illustrate the material of the previous sections. Bounds and extensions to unbounded cost and multichain structures are given in Section 8. Equipped with this probabilistic representation of solutions, we embark on investigating smoothness properties of the solutions to the parametrized problem. Methods for proving continuity and Lipschitz continuity are developed in Section 9 and 10, respectively.

To close, we note that most of the ideas which are discussed here in the context of countable Markov chains have extensions to fairly general state spaces. This is achieved by means of the so-called splitting technique [21, 22] which in essence guarantees the existence of an atom.

2. THE POISSON EQUATION AND ITS ASSOCIATED MARTINGALE

First, a few words on the notation used throughout the paper: The set of all real numbers is denoted by \( \mathbb{R} \) and \( 1[A] \) stands for the indicator function of a set \( A \). Unless otherwise stated, \( \lim_t, \underline{\lim}_t \) and \( \overline{\lim}_t \) are taken with \( t \) going to infinity. Moreover, the infimum over an empty set is taken to be \( \infty \) by convention. The mapping \( \delta : S \times S \to \mathbb{R} \) is defined by \( \delta(x, y) = 1 \) if \( x = y \), and \( \delta(x, y) = 0 \) otherwise. Finally, the notation \( \sum_{x \in S} \) is often abbreviated as \( \sum_z \).

2.1. The set-up

The notion of a Markov chain we adopt here is more general than the elementary one used in most applications. We do so with the view of broadening the applicability of the material developed here, especially to problems of adaptive control for Markov chains [13, 14, 17, 18, 29, 30].

As stated earlier in the introduction, the state space is a countable set \( S \), and the one-step transition mechanism is given by the \( S \times S \) stochastic matrix \( P \equiv (p_{xy}) \), so that \( 0 \leq p_{xy} \leq 1 \) and \( \sum_y p_{xy} = 1 \) for all \( x \) and \( y \) in \( S \). We assume the existence of a measurable space \((\Omega, \mathcal{F})\) large enough
to carry all the probabilistic elements considered in this paper. In particular, let \( \{ \mathcal{F}_t, \ t = 0, 1, \ldots \} \) denote a filtration of \( \mathcal{F} \), i.e., a monotone increasing sequence of \( \sigma \)-fields contained in \( \mathcal{F} \) such that \( \mathcal{F}_t \subseteq \mathcal{F}_{t+1} \) for all \( t = 0, 1, \ldots \), and let \( \{ X_t, \ t = 0, 1, \ldots \} \) be a sequence of \( S \)-valued rvs which are \( \mathcal{F}_t \)-adapted, i.e., the rv \( X_t \) is \( \mathcal{F}_t \)-measurable for all \( t = 0, 1, \ldots \).

The Markovian structure of interest is defined by postulating the existence of a family \( \{ \mathbf{P}_x, \ x \in S \} \) of probability measures on \( \mathcal{F} \) such that for all \( x \) and \( y \) in \( S \), we have

\[
\mathbf{P}_x[X_0 = y] = \delta(x, y) \quad (2.1a)
\]

and

\[
\mathbf{P}_x[X_{t+1} = y \mid \mathcal{F}_t] = p_{X_t,y} \quad \mathbf{P}_x - a.s. \quad t = 0, 1, \ldots (2.1b)
\]

With any probability distribution \( \mu \) on \( S \), we associate a probability measure \( \mathbf{P}_\mu \) on \( \mathcal{F} \) by setting

\[
\mathbf{P}_\mu[A] := \sum_x \mu(x) \mathbf{P}_x[A], \quad A \in \mathcal{F}. \quad (2.2)
\]

Obviously, when \( \mu \) is the Dirac measure \( \delta_x \) concentrated at some \( x \) in \( S \), then \( \mathbf{P}_\mu \) reduces to \( \mathbf{P}_x \).

Using (2.1)–(2.2) we easily see that

\[
\mathbf{P}_\mu[X_0 = x] = \mu(x), \quad x \in S \quad (2.3a)
\]

and

\[
\mathbf{P}_\mu[X_{t+1} = y \mid \mathcal{F}_t] = p_{X_t,y}, \quad x, y \in S \quad \mathbf{P}_\mu - a.s. \quad t = 0, 1, \ldots (2.3b)
\]

Under \( \mathbf{P}_\mu \) the rvs \( \{ X_t, \ t = 0, 1, \ldots \} \) thus have the Markov property with respect to the filtration \( \{ \mathcal{F}_t, \ t = 0, 1, \ldots \} \), and are said to form a time-homogeneous \( \mathcal{F}_t \)-Markov chain with one-step transition matrix \( P \) and initial probability distribution \( \mu \). In many instances, we take \( \mathcal{F}_t \) to be the \( \sigma \)-field generated by the rvs \( X_0, \ldots, X_t \) for all \( t = 0, 1, \ldots \), in which case the definition above coincides with the elementary definition of a Markov chain.

From (2.1a)–(2.2) we readily conclude for \( \mu \)-a.s. all \( x \) in \( S \) that

\[
\mathbf{P}_\mu[A \mid X_0 = x] = \mathbf{P}_x[A], \quad A \in \mathcal{F} \quad (2.4)
\]

so that \( \mathbf{P}_x \) has the useful interpretation of conditional probability (under \( \mathbf{P}_\mu \) for any initial distribution measure \( \mu \)).

Throughout it will be convenient to denote by \( \mathbf{E}_\mu \) and \( \mathbf{E}_x \) the expectation operator associated with \( \mathbf{P}_\mu \) and \( \mathbf{P}_x \), respectively.
2.2. The Poisson equation

Let $c$ be a given Borel mapping $S \to \mathbb{R}$. Throughout, it is understood that a constant $J$ and a mapping $h : S \to \mathbb{R}$ constitute a solution pair to the Poisson equation (1.1) with forcing function $c$ whenever $h$ satisfies the integrability conditions

$$\sum_y p_{xy} |h(y)| < \infty, \quad x \in S \quad (2.5a)$$

and the relations

$$h(x) + J = c(x) + \sum_y p_{xy} h(y), \quad x \in S \quad (2.5b)$$

hold. The Poisson equation is termed homogeneous if $c \equiv 0$.

For any initial distribution $\mu$, we introduce several classes of $\mathbb{R}$-valued mappings defined on $S$. We say that the mapping $f : S \to \mathbb{R}$ is an element of

1. $\mathcal{I}_\mu$ if $E_\mu[|f(X_t)|] < \infty$ for all $t = 0, 1, \ldots$;
2. $\mathcal{B}_\mu$ if $\sup_t E_\mu[|f(X_t)|] < \infty$;
3. $\mathcal{S}_\mu$ if $f$ belongs to $\mathcal{I}_\mu$ with $\lim_{t \to \infty} E_\mu[f(X_t)] = 0$; and
4. $\mathcal{U}_\mu$ if the rvs $\{f(X_t), \ t = 0, 1, \ldots\}$ are uniformly integrable under $P_\mu$.

When $\mu$ is the Dirac measure $\delta_x$ for some $x$ in $S$, we substitute the simpler notation $\mathcal{I}_x, \mathcal{B}_x, \mathcal{S}_x$ and $\mathcal{U}_x$ to $\mathcal{I}_{\delta_x}, \mathcal{B}_{\delta_x}, \mathcal{S}_{\delta_x}$ and $\mathcal{U}_{\delta_x}$, respectively.

For any initial distribution $\mu$, we readily see that

$$\mathcal{U}_\mu \subset \mathcal{B}_\mu \subset \mathcal{S}_\mu \subset \mathcal{I}_\mu \quad (2.6)$$

and for any $x$ in $S$ such that $\mu(x) > 0$, we have $\mathcal{I}_\mu \subset \mathcal{I}_x, \mathcal{B}_\mu \subset \mathcal{B}_x$ and $\mathcal{U}_\mu \subset \mathcal{U}_x$.

Since any mapping mapping $f : S \to \mathbb{R}$ can be viewed as a column vector $(f(x))$, the Poisson equation (1.1) can be written in matrix notation as

$$h + Je = c + Ph \quad (2.7)$$

where $e$ denotes the column vector with all its entries equal to one, i.e., $e(x) = 1$ for all $x$ in $S$. For any vector $f = (f(x))$ and any subset $E$ of $S$, denote by $f_E$ the restriction of $f$ to $E$ and similarly define $P_E$ as the restriction of $P$ to $E$. The identity matrix on $S$ is denoted by $I$.

2.3. A martingale property
Many of the general results on solutions to the Poisson equation can be traced back to the following observation.

**Lemma 2.1.** Let the pair \((h, J)\) be a solution to the Poisson equation (2.5) with forcing function \(c\). If the mapping \(h\) belongs to \(\mathcal{I}_\mu\) for some probability measure \(\mu\) on \(S\), then the following statements hold:

1. The forcing function \(c\) is necessarily an element of \(\mathcal{I}_\mu\); and
2. The rvs \(\{M_t, t = 0, 1, \ldots\}\) defined by \(M_0 := h(X_0)\) and

\[
M_{t+1} := h(X_{t+1}) + \sum_{s=0}^{t} c(X_s) - (t + 1)J \quad t = 0, 1, \ldots (2.8)
\]

form an integrable \((\mathbb{P}_\mu, \mathcal{F}_t)\)-martingale sequence.

**Proof.** Invoking the Markov property, we can reformulate the Poisson equation (2.5) as

\[
h(X_t) + J = c(X_t) + \mathbb{E}_\mu[h(X_{t+1})|\mathcal{F}_t] \quad t = 0, 1, \ldots (2.9)
\]

and the \(\mathbb{P}_\mu\)-integrability of the rvs \(\{c(X_t), t = 0, 1, \ldots\}\) follows from the assumption on \(h\). This proves Claim 1.

To establish Claim 2, we first conclude from the first part of the proof that the rvs \(\{M_t, t = 0, 1, \ldots\}\) are well defined and indeed \(\mathbb{P}_\mu\)-integrable. From (2.8), we then get

\[
\mathbb{E}_\mu[M_{t+1}|\mathcal{F}_t] = \mathbb{E}_\mu[h(X_{t+1})|\mathcal{F}_t] + \sum_{s=0}^{t} c(X_s) - (t + 1)J \quad t = 0, 1, \ldots (2.10)
\]

because the rvs \(X_0, \ldots, X_t\) are all \(\mathcal{F}_t\)-measurable, and the martingale property readily follows from (2.9).

\[\blacksquare\]

### 3. UNIQUENESS RESULTS

In this section, we have collected several uniqueness results for the Poisson equation (2.5). In that respect, we first note that if the pair \((h, J)\) is a solution to the Poisson equation, so is the pair \((h + \alpha e, J)\) for any constant \(\alpha\). In other words, uniqueness can only be obtained up to an additive constant. We also observe that for \(c\) in \(\mathcal{I}_\mu\), the definition

\[
J(\mu) := \lim_t \mathbb{E}_\mu \left[ \frac{1}{t+1} \sum_{s=0}^{t} c(X_s) \right] \quad (3.1)
\]
is well posed. The next lemma is a version of a standard result from the theory of MDPs under a long-run average criterion [9,26], [30, Lemma 3.1].

**Lemma 3.1.** Let the pair \((h, J)\) be a solution to the Poisson equation (2.5) with forcing function \(c\). If the mapping \(h\) belongs to \(S_\mu\) for some probability measure \(\mu\) on \(S\), then

\[
J = J(\mu) = \lim_t \mathbb{E}_\mu \left[ \frac{1}{t + 1} \sum_{s=0}^{t} c(X_s) \right].
\] (3.2)

**Proof.** Since \(h\) is an element of \(S_\mu\), it is also an element of \(I_\mu\) by virtue of (2.6). By Claim 2 of Lemma 2.1 we readily obtain the equalities \(\mathbb{E}_\mu[M_0] = \mathbb{E}_\mu[M_{t+1}]\) for all \(t = 0, 1, \ldots\) or, equivalently, in expanded form,

\[
\mathbb{E}_\mu[h(X_0)] = \mathbb{E}_\mu[h(X_{t+1})] + \mathbb{E}_\mu \left[ \sum_{s=0}^{t} c(X_s) \right] - (t + 1)J.
\] (3.3)

Some simple rearrangements yield

\[
\mathbb{E}_\mu \left[ \frac{1}{t + 1} \sum_{s=0}^{t} c(X_s) \right] = J - \frac{1}{t + 1} \left\{ \mathbb{E}_\mu[h(X_{t+1})] - \mathbb{E}_\mu[h(X_0)] \right\}
\] (3.4)

and the result (3.2) is now immediate upon letting \(t \uparrow \infty\) in (3.4) since \(h\) is an element of \(S_\mu\). \(\blacksquare\)

If the Poisson equation (2.5) admits a solution \((h, J)\) with \(h\) bounded, then \(c\) is bounded, so that both \(c\) and \(h\) belong to \(U_\mu\) (thus \(S_\mu\)) for any initial distribution \(\mu\). It then follows from Lemma 3.1 that \(J(\mu)\) is obtained as a limit which does not depend on the initial distribution \(\mu\).

The uniqueness of solutions to the Poisson equation is now briefly studied in the class of “uniformly \(L_1\)-bounded” solutions, that is in \(B_\mu\) for some initial state distribution \(\mu\). If the state space contains a set \(I\) of isolated states which are not reachable from \(S \setminus I\) and if \(\mu(I) = 0\), then clearly the chain never visits the states in \(I\). To simplify the exposition we find it convenient to reformulate the problem on the reduced state space \(S - I\).

The next lemma is preparatory in nature and will greatly simplify the presentation: For \((h_1, J_1)\) and \((h_2, J_2)\) solution pairs to the Poisson equation (2.5), we define

\[
\Delta J := J_1 - J_2 \quad \text{and} \quad \Delta h(x) := h_1(x) - h_2(x), \quad x \in S.
\] (3.5)
Lemma 3.2. Let \((h_1, J_1)\) and \((h_2, J_2)\) be two solutions of the Poisson equation (2.5). If \(\Delta h\) belongs to \(I_{\mu}\) for some probability measure \(\mu\) on \(S\), then the rvs \(\{\Delta h(X_t) - \Delta Jt, t = 0, 1, \ldots\}\) form a \((P_{\mu}, F_t)\)-martingale sequence with

\[
\Delta J = \frac{1}{s} \left\{ E_{\mu}[\Delta h(X_{t+s})] - E_{\mu}[\Delta h(X_t)] \right\},
\]

for \(t = 0, 1, \ldots; s = 1, 2, \ldots\) (3.6)

Proof. Denoting by \(\{M^i_t, \ t = 0, 1,\ldots\}\) the rvs (2.11) associated with the solution pair \((h_i, J_i)\), \(i = 1, 2\), we define the rvs \(\{\Delta M_t, \ t = 0, 1,\ldots\}\) by

\[
\Delta M_t := M^2_t - M^1_t = \Delta h(X_t) - t\Delta J.
\]

(3.7)

It is plain that \((\Delta h, \Delta J)\) is a solution to the homogeneous Poisson equation \(\Delta h + \Delta J e = P \Delta h\). Applying Lemma 2.1 to this Poisson equation, we conclude that the rvs \(\{\Delta M_t, \ t = 0, 1,\ldots\}\) indeed form an integrable \((P_{\mu}, F_t)\)-martingale sequence, whence \(E_{\mu}[\Delta M_{t+s}] = E_{\mu}[\Delta M_t]\) for all \(s, t = 0, 1, \ldots\). In expanded form, these equalities become

\[
E_{\mu}[\Delta h(X_{t+s})] - (t+s)\Delta J = E_{\mu}[\Delta h(X_t)] - t\Delta J
\]

(3.8)

\(s, t = 0, 1, \ldots\)

and we obtain (3.6) after simple rearrangements.

The basic uniqueness result can now be developed.

Theorem 3.3. Let \((h_1, J_1)\) and \((h_2, J_2)\) be two solutions of the Poisson equation (2.5).

1. If \(\Delta h\) belongs to \(S_{\mu}\) for some probability measure \(\mu\) on \(S\), then \(J_1 = J_2\);

2. If in addition \(\Delta h\) is an element of \(B_{\mu}\), then \(\Delta h\) is constant on each recurrent class of the Markov chain \(P_{\mu}\).

Proof. If \(\Delta h\) belongs to \(S_{\mu}\), then its is also an element of \(I_{\mu}\), and Claim 1 follows by letting \(s \uparrow \infty\) in (3.6) and using the fact that \(\Delta h\) belongs to \(S_{\mu}\).

The proof of Claim 2 starts with the observation (2.6) made earlier that since \(\Delta h\) is an element of \(B_{\mu}\), it it is also an element of \(S_{\mu}\). Therefore, \(J_1 = J_2\) by Claim 1 and the rvs \(\{\Delta h(X_t), \ t = 0, 1,\ldots\}\) form a \((P_{\mu}, F_t)\)-martingale sequence with \(\sup_t E_{\mu}[|\Delta h(X_t)|] < \infty\). By a standard martingale convergence theorem [6,10], the martingale sequence \(\{\Delta h(X_t), \ t = 0, 1,\ldots\}\) converges \(P_{\mu}\)-a.s. to a proper rv.

If all the states in \(S\) form a single recurrent class under \(P\), then any two states in \(S\), say \(x\) and \(y\), are visited infinitely often \(P_{\mu}\)-a.s. It is now plain that \(h(x) = h(y)\) by virtue of the \(P_{\mu}\)-a.s. convergence of the martingale \(\{\Delta h(X_t), \ t = 0, 1,\ldots\}\), and \(\Delta h\) is therefore constant on \(S\).
More generally, let \( R \) be a recurrence class under \( P \), i.e., a closed irreducible set of recurrent states. Since \( p_{x,y} = 0 \) for all \( x \) in \( R \) and \( y \) not in \( R \), (2.5) implies

\[
h_{i,R} + Je_R = c_R + P_R h_{i,R}, \quad i = 1, 2. \tag{3.9}
\]

The matrix \( P_R \) can be interpreted as the matrix of one-step transition probabilities for an irreducible Markov chain on \( R \) with all its states recurrent, and the problem is now reduced to the previously considered case. Therefore, \( h_{1,R} - h_{2,R} \) is constant on \( R \) and the proof is complete. \( \blacksquare \)

Under conditions weaker than the ones assumed in Theorem 3.3 we can obtain a refinement of Claim 1 of Theorem 3.3.

**Corollary 3.4.** Let \( (h_1, J_1) \) and \( (h_2, J_2) \) be two solutions to the Poisson equation (2.5). If for some probability measure \( \mu \) on \( S \), \( h_1 \) belongs to \( S_\mu \) and \( h_2 \) belongs to \( I_\mu \), then

\[
\lim_t \frac{1}{t} E_\mu [h_2(X_t)] = J_2 - J_1 . \tag{3.10}
\]

**Proof.** First we note that if \( h_1 \) is an element of \( S_\mu \) and if \( h_2 \) belongs to \( I_\mu \), then \( \Delta h \) belongs to \( I_\mu \). By Lemma 3.2 we get

\[
\Delta J = \frac{1}{t} \left\{ E_\mu [\Delta h(X_t)] - E_\mu [\Delta h(X_0)] \right\} \quad t = 1, 2, \ldots \tag{3.11}
\]

and (3.10) follows upon letting \( t \uparrow \infty \) in (3.11) and using the fact that \( h_1 \) is an element of \( S_\mu \). The existence of the limit is a consequence of the equalities (3.11). \( \blacksquare \)

It is very easy to demonstrate the non-uniqueness of solutions to the Poisson equation: Consider the Markov chain \( P \equiv (p_{xy}) \) on the non-negative integers \( \mathbb{N} \) with \( p_{x,x+1} = 1, \ x = 0, 1, \ldots \), and let \( c \equiv 0 \). Then \( (h_2, J_2) \equiv (0, 0) \) is obviously a solution to the Poisson equation with \( h_1(0) = 0 \). However, the pair \( (h_2, J_2) \equiv (x, 1) \) is also a solution to the Poisson equation with \( h_2(0) = 0 \). For all \( t = 0, 1, \ldots \), we have \( Y_t = X_0 + t \) \( P_\mu \)-a.s., whence \( E_\mu [h_2(X_t)] = E_\mu [X_0] + t \), and under the condition \( E_\mu [X_0] < \infty \), \( h_2 \) is an element of \( I_\mu \), but not of \( S_\mu \). In fact, (3.10) holds as \( \lim_t \frac{1}{t} E_\mu [h_2(X_t)] = 1 \neq 0 \).

In Section 7 we discuss the non-uniqueness issue for a more elaborate example of a positive recurrent system.
Although in practice it might be hard to verify the $L_1$-boundedness conditions of Theorem 3.3, a simple characterization of the set $B_\mu$ is available in a special yet important case. Recall that a probability measure $\gamma$ on $B(S)$ is an invariant measure for the one-step transition matrix $P$ if

$$\gamma(x) = \sum_y \gamma(y)p_{yx}, \quad x \in S.$$  \hfill (3.12)

Under $P_\gamma$ the Markov chain $\{X_t, \ t = 0, 1,\ldots\}$ forms a strictly stationary sequence with one-dimensional marginal distribution $\gamma$, so that the following characterization is immediate.

**Lemma 3.5.** If $\gamma$ is an invariant probability measure for the one-step transition matrix $P$, then $I_\gamma = B_\gamma = U_\gamma = L_1(S,B(S),\gamma)$.

In [7] Derman and Veinott consider the uniqueness issue for Markov chains with a single positive recurrent class (in which case the invariant measure $\gamma$ is unique). They show uniqueness in the class $DV$ of mappings $f : S \to \mathbb{R}$ such that

$$\mathbb{E}_x \left[ \sum_{t=0}^{T-1} |f(X_t)| \right] < \infty, \quad x \in S$$  \hfill (3.13)

where $T := \inf\{t > 0 : X_t = z\}$ for some distinguished recurrent state $z$. Under these assumptions, for every mapping $f : S \to \mathbb{R}$, we conclude by standard results on Markov chains [5] that

$$\mathbb{E}_\gamma[|f(X_t)|] = \frac{\mathbb{E}_x \left[ \sum_{t=0}^{T-1} |f(X_t)| \right]}{\mathbb{E}_x[T]}.$$  \hfill (3.14)

Therefore, the inclusion $DV \subset B_\gamma$ holds, so that even in the case of a chain with a single positive recurrent class, the conditions of [7] are more stringent than the ones given in Theorem 3.3.

4. DECOMPOSITION RESULTS

4.1. A state decomposition result

With the uniqueness result of Theorem 3.3 in mind, we consider the decomposition of the countable set $S$ induced by the recurrence structure of $P$: Let $Tr$ denote the (possibly empty) set of transient states, and let $\{R_\alpha, \ \alpha \in A\}$, for some countable index set $A$, denote the recurrent components. The sets $\{Tr, R_\alpha, \ \alpha \in A\}$ form a partition of $S$. Moreover, for all $\alpha$ in $A$, $p_{xy} = 0$ for $x$ in $R_\alpha$ and
y not in $R_\alpha$, and the restriction $P_\alpha$ of $P$ to the recurrent class $R_\alpha$ is irreducible and recurrent on it. With the vector notation of Section 2, (2.5) can now be partitioned as

$$h_{R_\alpha} + J e_{R_\alpha} = c_{R_\alpha} + P_\alpha h_{R_\alpha}, \quad \alpha \in A$$

$$h_{T_r} + J e_{T_r} = c_{T_r} + \sum_{\alpha \in A} T_\alpha h_{R_\alpha} + P_{T_r} h_{T_r}$$

(4.1a) (4.1b)

where the matrices $\{T_\alpha, \alpha \in A\}$ and $P_{T_r}$ are determined from the decomposition of $P$ associated with the sets $\{T_r, R_\alpha, \alpha \in A\}$.

The decomposition (4.1) motivates introducing the following family of Poisson equations

$$h_\alpha + J_\alpha e_{R_\alpha} = c_{R_\alpha} + P_\alpha h_\alpha, \quad \alpha \in A$$

$$\tilde{h} + J e_{T_r} = \tilde{c} + P_{T_r} \tilde{h}$$

(4.2a) (4.2b)

where for each $\alpha$ in $A$, $h_\alpha$ is a mapping $R_\alpha \to \mathbb{R}$, while $\tilde{c}$ and $\tilde{h}$ are mappings $T_r \to \mathbb{R}$, with

$$\tilde{c} = c_{T_r} + \sum_{\alpha \in A} T_\alpha h_\alpha.$$  

(4.3)

The next result shows in what sense the solutions to the projected Poisson equations (4.2) determine the solution to the original equation (2.5). The proof is a simple consequence of (4.1) and (4.2), and is omitted in the interest of brevity.

**Theorem 4.1.** The Poisson equation (2.5) has a solution if and only if the following two conditions hold:

1. For each $\alpha$ in $A$, the Poisson equation (4.2a) on $R_\alpha$ has a solution $(h_\alpha, J_\alpha)$ such that $J_\alpha = J$ for some scalar $J$ independent of $\alpha$ and

$$\sum_{\alpha \in A} T_\alpha |h_\alpha| < \infty;$$

(4.4)

2. The Poisson equation (4.2b), with forcing function $\tilde{c}$ given by (4.3) has a solution $(\tilde{h}, \tilde{J})$ such that $\tilde{J} = J$.

A solution pair to (2.5) is necessarily of the form $(h, J)$ with $h$ determined by $h_{R_\alpha} = h_\alpha$ for all $\alpha$ in $A$ and $h_{T_r} = \tilde{h}$.

Condition (4.4), which is automatically satisfied when $S$ is finite, guarantees that $\tilde{c}$ (and therefore (4.2b)) is well defined.

**4.2. A Green-like decomposition**
Let \((h_1, J_1)\) and \((h_2, J_2)\) be two solutions of the Poisson equation (4.2) with forcing functions \(c_1\) and \(c_2\), respectively. Then for any \(\beta \in \mathbb{R}\), \((h, J) := (\beta h_1 + h_2, \beta J_1 + J_2)\) is a solution to the Poisson equation (2.5) with forcing function \(\beta c_1 + c_2\). Indeed, by definition,

\[
 h(x) + J = \beta (h_1(x) + J_1) + (h_2(x) + J_2)
 = \beta \left( c_1(x) + \sum_y p_{xy} h_1(y) \right) + \left( c_2(x) + \sum_y p_{xy} h_2(y) \right)
 = (\beta c_1(x) + c_2(x)) + \sum_y p_{xy} (\beta h_1(y) + h_2(y)), \quad x \in S
\]  

(4.5)

where the last sum is well defined owing to the definition of a solution (2.5b).

This simple fact can be used as follows: For each \(v\) in \(S\), define the function \(c_v : S \to \mathbb{R}\) by \(c_v(x) := \delta(v; x)\) for all \(x\) in \(S\), and let \((h_v, J_v)\) denote a solution to the Poisson equation with forcing function \(c_v\). The obvious decomposition

\[
 c(x) = \sum_v c(v) c_v(x), \quad x \in S
\]  

(4.6)

then leads naturally to the formal representation

\[
 J = \sum_v c(v) J_v \quad \text{and} \quad h(x) = \sum_v c(v) h_v(x), \quad x \in S.
\]  

(4.7)

It remains then to check that (4.7) indeed defines a legitimate solution. In view of (4.5), this is the case whenever \(c\) is constant except at a finite number of points. In the more general case, this check can be done through the constructive arguments of Corollary 6.2, or through the verification result of Theorem 6.4. Such a calculation is performed directly in Section 7.

5. FINITE STATE SPACES

A complete picture of the solution to the Poisson equation (2.5) is available when \(S\) is a finite set, and can be found in [2, 31]. In the finite space case any solution necessarily belongs to \(\mathcal{U}_\mu\) for every initial probability distribution \(\mu\). Let \(P^*\) denote the stochastic matrix defined by

\[
 P^* := \lim_{t \to \infty} \frac{1}{t + 1} \sum_{s=0}^{t} P^s;
\]  

(5.1)

its existence is guaranteed by classical results from the theory of Markov chains [2, 31]. Because the matrix \(I - P + P^*\) is invertible, the definition

\[
 h := (I - P + P^*)^{-1} (I - P^*) c
\]  

(5.2)
is well posed. The easy identities \( P^*P = PP^* = P^*P^* = P^* \) lead after some simple algebra to the relation

\[
h + P^*c = c + Ph.
\]

(5.3)

A simple comparison of (5.3) with (2.5) suggests that \( h \) defined by (5.2) will solve the Poisson equation (2.5) whenever the vector \( P^*c \) is proportional to \( c \), i.e., all the components of the vector \( P^*c \) are identical.

To investigate the matter further, we introduce the canonical decomposition of \( S \) into the recurrent and transient components induced by \( P \), as already done in Section 4. Here, it can be assumed that \( P \) induces \( m \) recurrent classes, say \( R_1, \ldots, R_m \), as well as a (possibly empty) set \( Tr \) of transient states, with the sets \( \{R_1, \ldots, R_m, Tr\} \) forming a partition of \( S \). For any vector \( f \), let \( f_k \) denote the restriction of \( f \) to \( R_k \), \( k = 1, \ldots, m \).

Recall that \( p_{xy} = 0 \) for \( x \) in \( R_k \) and \( y \) not in \( R_k \), and the restriction \( P_k \) of \( P \) to the recurrent class \( R_k \) is irreducible and positive recurrent on it. Possibly upon rearranging \( P \) into a block lower triangular form, we see that the restriction \((P^*)_k\) of \( P^* \) to \( R_k \) coincides with \((P_k)^*\) given by

\[
(P_k)^* := \text{lim}_{t \to \infty} \frac{1}{t+1} \sum_{s=0}^t P_k^s, \quad k = 1, \ldots, m
\]

(5.4)

with all its rows being identical to the long-run probability distribution associated with the irreducible chain \( P_k \). Consequently, \((P^*c)_k = J_k e_k\) where the scalar \( J_k \) depends on the class \( R_k \). Therefore (5.3) can be decomposed as

\[
h_k + J_k e_k = c_k + P_k h_k, \quad k = 1, \ldots, m
\]

(5.5a)

\[
h_{Tr} + (P^*c)_{Tr} = c_{Tr} + \sum_{k=1}^m T_k h_k + Trh_{Tr}
\]

(5.5b)

where the matrices \( T_1, \ldots, T_m \) and \( Tr \) are chosen appropriately from the decomposition of \( P \) associated with the sets \( \{R_1, \ldots, R_m, Tr\} \).

**Theorem 5.1.** The pair \((h, J)\) is a solution to the Poisson equation (2.5) if and only if the conditions

\[
J_1 = \ldots = J_m = J \quad \text{and} \quad (P^*c)_{Tr} = Je_{Tr}
\]

(5.6)

hold, in which case \( h \) is given uniquely up to an additive constant by (5.2), and \( J \) is the constant appearing in (5.6). The conditions (5.6) are satisfied when the Markov chain \( P \) has a single recurrent class.
Proof. The first part is immediate from the discussion given earlier since \( P^* c = Je \) under (5.6). The uniqueness follows from Theorem 3.2 and from the fact that \( I - Tr \) is invertible. To conclude the last part, it suffices to observe that under the assumption of a single recurrent class \( R_1 \) for the Markov chain \( P \), the rows of \( P^* \) are all identical and of the form \((\nu, 0_{Tr})\) where \( \nu \) coincides with the long-run probability distribution vector associated with the irreducible chain \( P_1 \).

In fact, (5.6a) implies (5.6b) as can be seen from the discussion in Theorem 6.3 and the remark preceding its proof.

6. A PROBABILISTIC FORMULA FOR SOLUTIONS

Consider now the situation where the state space \( S \) is countably infinite. The matrix \( P^* \) is still well defined, but in general the invertibility of \( I - P + P^* \) cannot be guaranteed anymore owing to the intricate nature of the recurrence structures for Markov chains over countably infinite state spaces. As a result, the algebraic discussion of Section 5 cannot be carried through.

In some situations however, probabilistic arguments can be used to prove the existence of a solution pair to the Poisson equation. Such a situation arises when there exists a distinguished state in \( S \), say \( z \), which is positive recurrent in a sense made precise below. In this more restricted set-up, a possible approach would mimic the arguments of [26, Section 6.7], and would yield the solution as the limit of the discounted cost associated with \( c \), when the discount factor tends to 1. This line of arguments was developed in [28] and does yield a probabilistic representation of the solution already obtained by Derman and Veinott [7] through algebraic means.

In this paper, we take a different route for deriving this probabilistic representation of solutions to the Poisson equation. We do so in several steps by exploiting the martingale property of Lemma 2.1. To precisely state the conditions, we define the first passage time to the state \( z \) as the \( F_t \)-stopping time \( T \) given by

\[
T := \inf\{ t > 0 : X_t = z \}. \tag{6.1}
\]

The recurrence condition \((R)\) enforced thereafter is the finite mean condition

\[
(R) \quad T(x) := \mathbb{E}_x[T] < \infty, \quad x \in S.
\]

The condition \((R)\) is automatically satisfied when the set \( S \) is finite and the Markov chain \( P \) admits a single (positive) recurrent class decomposition \( S = R \cup Tr \) into a set \( R \) of positive recurrent states and a (possibly empty) set \( Tr \) of transient states. However, when the set \( S \) is not finite, the condition \((R)\) is far more stringent. Indeed, not only does it imply the single class decomposition...
$S = R \cup Tr$, but it also prohibits the chain from wandering too long or exclusively amongst the transient states. We relax the first restriction in Section 8.

We also find it convenient to consider the following integrability condition (I), where

$$C_*(x) := \mathbb{E}_x \left[ \sum_{t=0}^{T-1} |c(X_t)| \right] < \infty, \quad x \in S. \quad (6.2)$$

Under (I) the quantities

$$C(x) := \mathbb{E}_x \left[ \sum_{t=0}^{T-1} c(X_t) \right], \quad x \in S \quad (6.3)$$

are well defined. Under the recurrence condition (R), any bounded mapping $c$ will satisfy the integrability condition (I); in fact the conditions (R) and (I) coincide for $c(x) = 1$ for all $x$ in $S$.

The next result is a consequence of the martingale property given in Lemma 2.1.

**Theorem 6.1.** Assume the recurrence condition (R) to hold and let $(h, J)$ be a solution pair to the Poisson equation (2.5). If $h$ is an element of $\mathcal{I}_x$ for some $x$ in $S$, then

$$\lim_n \left\{ \mathbb{E}_x [1[n < T]h(X_n)] + \mathbb{E}_x \left[ \sum_{t=0}^{T \wedge n-1} c(X_t) \right] \right\} = JT(x) + h(x) - h(z). \quad (6.4)$$

**Proof.** By Lemma 2.1, the rvs $\{M_t, t = 0, 1, \ldots\}$ given by (2.8) form a $(P_x, \mathcal{F}_t)$-martingale. By Doob's Optional Sampling Theorem [6, 10], the stopped process $\{M_{T \wedge n}, n = 0, 1, \ldots\}$ is also a $(P_x, \mathcal{F}_{T \wedge n})$-martingale, so that

$$\mathbb{E}_x[M_{T \wedge n}] = \mathbb{E}_x[M_0] = h(x). \quad n = 0, 1, \ldots \quad (6.5)$$

By Lemma 2.1 we see that $c$ is an element of $\mathcal{I}_x$ because $h$ belongs to $\mathcal{I}_x$, and therefore, for all $n = 0, 1, \ldots$, the three rvs $h(X_{T \wedge n})$, $T \wedge n$ and $\sum_{t=0}^{T \wedge n-1} c(X_t)$ are integrable under $P_x$. From the definition of $M_{T \wedge n}$ we conclude by direct inspection of (6.5) that

$$h(x) = \mathbb{E}_x \left[ h(X_{T \wedge n}) - (T \wedge n)J + \sum_{t=0}^{T \wedge n-1} c(X_t) \right] = h(x)P_x[T \leq n] + \mathbb{E}_x [1[T > n]h(X_n)] - J\mathbb{E}_x[T \wedge n] + \mathbb{E}_x \left[ \sum_{t=0}^{T \wedge n-1} c(X_t) \right]. \quad (6.6)$$

Under (R), we have $\lim_n P_x[T \leq n] = 1$, whereas $\lim_n \mathbb{E}_x[T \wedge n] = T(x)$ by monotone convergence, and the result (6.4) follows upon letting $n \uparrow \infty$ in (6.6).
As we impose additional conditions, we see the form of the probabilistic representation emerge from the relation (6.4).

**Corollary 6.2.** Assume the recurrence condition (R) to hold, and let \((h, J)\) be a solution to the Poisson equation (2.5). If \(h\) belongs to \(\mathcal{U}_x\) for some \(x\) in \(S\), then the relation

\[
h(x) = \lim_n \mathbb{E}_x \left[ \sum_{t=0}^{T \wedge n-1} c(X_t) \right] - JT(x) + h(z) \tag{6.7}
\]

holds. If in addition, the integrability condition (I) holds, then

\[
h(x) = C(x) - T(x)J + h(z). \tag{6.8}
\]

**Proof.** Under (R), we have \(\lim_n \mathbb{P}_x[T > n] = 0\) and the uniform integrability of the rvs \(\{h(X_t), t = 0, 1, \ldots\}\) under \(\mathbb{P}_x\) then implies \(\lim_n \mathbb{E}_x [1[T > n]h(X_n)] = 0\), so that (6.7) follows from (6.4). Under (I) we get

\[
\lim_n \mathbb{E}_x \left[ \sum_{t=0}^{T \wedge n-1} c(X_t) \right] = \mathbb{E}_x \left[ \sum_{t=0}^{T-1} c(X_t) \right] = C(x) \tag{6.9}
\]

by dominated convergence, and (6.8) is an immediate consequence of (6.7) and (6.9). \(\blacksquare\)

By carefully inspecting this last proof, we can extract additional information on the interaction between the uniform integrability of solutions and the integrability condition (6.2): We define the positive and negative parts of the forcing function \(c\) by \(c_\pm(x) := \max\{0, \pm c(x)\}\) for all \(x\) in \(S\), so that \(c(x) = c_+(x) - c_-(x)\) and \(|c(x)| = c_+(x) + c_-(x)\). In analogy with (6.3), we introduce the quantities

\[
C_\pm(x) := \mathbb{E}_x \left[ \sum_{t=0}^{T-1} c_\pm(X_t) \right], \quad x \in S \tag{6.10}
\]

which are both well defined, although possibly infinite. The relation \(C(x) = C_+(x) - C_-(x)\) holds provided at least one of the quantities \(C_+(x)\) and \(C_-(x)\) is finite, while the equality \(C_+(x) = C_+(x) + C_-(x)\) is always valid.

**Corollary 6.3.** Assume the recurrence condition (R) to hold, and let \((h, J)\) be a solution to the Poisson equation (2.5). If \(h\) belongs to \(\mathcal{U}_x\) for some \(x\) in \(S\), then the relation

\[
h(x) + C_-(x) = C_+(x) - JT(x) + h(z) \tag{6.11}
\]
holds. If in addition, c is either bounded above or below, then \( C_+ (x) \) is finite and the relation (6.8) holds.

**Proof.** We go back to the proof of Theorem 6.1, and observe that for all \( n = 0, 1 \ldots \) the noted integrability of the rv \( \sum_{t=0}^{T \wedge n-1} c(X_t) \) implies that of the rvs \( \sum_{t=0}^{T \wedge n-1} c_\pm (X_t) \). Using this fact we can rewrite (6.6) as

\[
h(x) + E_x \left[ \sum_{t=0}^{T \wedge n-1} c_-(X_t) \right] \\
= h(z)P_x[T \leq n] + E_x [1[T > n]h(X_n)] - J E_x[T \wedge n] + E_x \left[ \sum_{t=0}^{T \wedge n-1} c_+(X_t) \right] \tag{6.12}
\]

and the proof now proceeds as before: Under (R), we have \( \lim_n P_x[T \leq n] = 1 \), and \( \lim_n E_x[T \wedge n] = T(x) \) by monotone convergence. Moreover, the uniform integrability of the rvs \( \{ h(X_t), t = 0, 1, \ldots \} \) under \( P_x \) implies \( \lim_n E_x [1[T > n]h(X_n)] = 0 \), and \( C_\pm (x) = \lim_n E_x \left[ \sum_{t=0}^{T \wedge n-1} c_\pm (X_t) \right] \) by monotone convergence. The result (6.11) follows from these facts upon letting \( n \uparrow \infty \) in (6.12).

To establish the second statement, we note that \( c \) being either bounded above or below implies that at least one of the quantities \( C_+ (x) \) and \( C_- (x) \) is finite, whence both are necessarily finite in view of the relation (6.11).

Corollary 6.2 states that under conditions (R) and (I), any "uniformly integrable" solution \( (h, J) \) of the Poisson equation is necessarily given by (6.8) (up to an additive constant). In a sense, we can view (6.8) as the "minimal" solution to (2.5). However, as we next show, (6.8) does define a solution even when there may exist no uniformly integrable one.

**Theorem 6.4.** Assume both the recurrence condition (R) and the integrability condition (I) to hold. Then the pair \( (h, J) \) given by

\[
J = \frac{C(z)}{T(z)} \quad \text{and} \quad h(x) = C(x) - J \cdot T(x), \quad x \in S. \tag{6.13}
\]

is a solution to the Poisson equation (2.5) with \( h(z) = 0 \).

When the state space \( S \) is finite and the chain has a single recurrent class, (6.13) provides a probabilistic interpretation for the solution described through purely algebraic means in [2, 31].

Although condition (R) may seem quite restrictive, it is in some sense close to being necessary. Indeed, as shown by Cavazos-Cadena [4, Cor. 2.1-2.2, p. 105], if the Poisson equation admits a
bounded solution for every cost $c$ which vanishes at infinity, then (i) there exists a single recurrent class, which is necessarily positive recurrent; and (ii) a condition stronger than (R) holds, namely $\sup_x T(x) < \infty$.

**Proof.** The algebraic manipulations below are validated through the following summability conditions

$$\sum_{y \neq x} p_{xy} T(y) < \infty \quad \text{and} \quad \sum_{y \neq x} p_{xy} |C(y)| < \infty, \quad x \in S. \quad (6.14)$$

In view of the comment following (6.3), we only need to establish the second condition in (6.14) as the first one reduces to it when $c \equiv 1$. By the Markov property, we get

$$C_*(x) = |c(x)| + \sum_{y \neq x} p_{xy} C_*(y), \quad x \in S \quad (6.15)$$

and the second summability condition in (6.14) follows from the integrability condition (I) since $|C(x)| \leq C_*(x)$ for all $x$ in $S$.

The arguments that lead to (6.15) also show that

$$C(x) = c(x) + \sum_{y \neq x} p_{xy} C(y), \quad x \in S \quad (6.16)$$

and

$$T(x) = 1 + \sum_{y \neq x} p_{xy} T(y), \quad x \in S. \quad (6.17)$$

For any scalar $J$, we use (6.16)–(6.17) to write

$$C(x) - J \cdot T(x) = \left[ c(x) + \sum_{y \neq x} p_{xy} C(y) \right] - J \cdot \left[ 1 + \sum_{y \neq x} p_{xy} T(y) \right], \quad x \in S. \quad (6.18)$$

Now, with the choice $J = C(z)/T(z)$, (6.18) becomes

$$\left[ C(x) - J \cdot T(x) \right] + J = c(x) + \sum_{y \neq x} p_{xy} [C(y) - J \cdot T(y)]$$

$$= c(x) + \sum_{y \neq x} p_{xy} [C(y) - J \cdot T(y)], \quad x \in S \quad (6.19)$$

and $(h, J)$ is indeed a solution of the Poisson equation with $J = C(z)/T(z)$ and $h(z) = 0$.

We conclude this section by showing in what sense uniform integrability comes close to being necessary to ensure uniqueness. This will follow from the next result which is a simple consequence of (6.4) once it is observed that $C(x) = \lim_n \mathbb{E}_x \left[ \sum_{t=0}^{T^{\wedge} n-1} c(X_t) \right]$ whenever $C_*(x)$ is finite.
Corollary 6.5. Assume the recurrence condition (R) to hold and let \((h, J)\) be a solution pair to the Poisson equation (2.5). If \(h\) is an element of \(I_x\) for some \(x\) in \(S\) and if \(C_x(x)\) is finite, then

\[
\lim_n E_x [1[n < T] h(X_n)] = h(x) - h(z) - [C(x) - JT(x)].
\] (6.20)

We see from (6.20) that this solution \(h\) in \(I_x\) coincides with that given by (6.13) provided \(\lim_n E_x [1[n < T] h(X_n)] = 0\), a condition reminiscent of uniform integrability (i.e., \(h\) in \(U_x\)) and indeed implied by it.

7. AN EXAMPLE

In this section we specialize the results obtained so far to a simple reflected random walk. The solution given by the probabilistic representation is computed explicitly, and shown to belong to \(B_\gamma = U_\gamma\) where \(\gamma\) is the invariant distribution) whenever the forcing function \(c\) is an element of \(B_\gamma\). In that case, we also identify a class of solutions which are not uniformly integrable; in fact, we calculate all solutions to the Poisson equation, thereby exhibiting non-uniqueness for a positive recurrent Markov chain. The calculations are carried out in Appendix A below.

The situation considered here is that of a random walk on the non-negative integers with reflection, i.e., \(S = \mathbb{N}\) and

\[
p_{0,0} = p_{x+1,x} = 1 - p := q \quad \text{and} \quad p_{x,x+1} = p, \quad x = 0, 1, \ldots (7.1)
\]

for some \(0 < p < 1\). With a queueing-theoretic interpretation in mind, we define \(\rho := p/q\), and note that this Markov chain is positive recurrent—and condition (R) holds—whenever \(\rho < 1\) (or equivalently \(0 < p < 1/2\)). In that case, making use of the defining relation (3.16), we readily determine the invariant distribution \(\gamma\) to be

\[
\gamma(x) = (1 - \rho) \rho^x. \quad x = 0, 1, \ldots (7.2)
\]

For any forcing function \(c\), the Poisson equation (2.5) here takes the form

\[
ph(0) + J = ph(1) + c(0)
\]

and

\[
h(x + 1) + J = qh(x) + ph(x + 2) + c(x + 1). \quad x = 0, 1, \ldots (7.3)
\]

Before addressing the existence of solutions to (7.3), we show that such solutions are not unique. Indeed, if \((h_i, J_i), i = 1, 2\), are two solution pairs to (7.3), then their difference \((\Delta h, \Delta J)\) (in the
notation (3.5)) solves the homogeneous equation \( \Delta h + \Delta Je = P\Delta h \), which can be rewritten as
\[
p [\Delta h(1) - \Delta h(0)] = \Delta J
\]
and
\[
p [\Delta h(x + 2) - \Delta h(x + 1)] = \Delta J + q [\Delta h(x + 1) - \Delta h(x)]. \quad x = 0, 1, \ldots (7.4)
\]
For any value of \( \Delta J \) it is a simple matter to show that all the solutions to (7.4) are given by
\[
\Delta h(x) = \Delta h(0) + \frac{\Delta J}{p - q} \left[ \frac{1 - \rho^{-x}}{1 - \rho} + x \right], \quad x \in S
\] (7.5)
and parametrized by the initial condition \( \Delta h(0) \). Therefore, if \( (h_1, J_1) \) is a solution to (7.3), so is \( (h_1 + \Delta h, J_1 + \Delta J) \) for any choice of \( \Delta J \) (in \( \mathbb{R} \)) where \( \Delta h \) is given by (7.5) with that value of \( \Delta J \). In other words, even when all solutions to (7.3) are required to have identical initial conditions—a normalizing condition which dictates \( \Delta h(0) = 0 \) in (7.5)—we conclude that the solution set to (7.3) must necessarily be non-countable provided it is not empty. This non-uniqueness is independent of the choice of \( c \), and holds also when \( \rho \geq 1 \), i.e., the chain is null recurrent or transient.

When \( 0 < \rho < 1 \), we observe that \( \Delta h \) given by (7.5) can never belong to \( \mathcal{U}_\gamma \) unless \( \Delta J = 0 \), thereby confirming the uniqueness of solutions in \( \mathcal{U}_\gamma \), a result that derives from Theorem 3.3 (and independently from Corollary 6.2). Therefore, it now remains to determine conditions under which the solution in \( \mathcal{U}_\gamma \) exists.

With the representation (6.13) in mind, we take \( z = 0 \) and use (6.17) to obtain
\[
T(x) = \frac{q\delta(0,x) + x}{q-p}; \quad x = 0, 1, \ldots (7.6)
\]
calculations are outlined in Appendix A.

Next, intent on using the Green decomposition technique of Section 4.2, we compute for each \( v \) in \( S \) the cost per cycle function \( C_v \) associated with the cost \( c_v : S \to \mathbb{R} : x \to \delta(v,x) \). Since \( J_v = \gamma(v) \), we invoke (3.14) to get
\[
C_v(0) = J_v T(0) = \gamma(v) \frac{\rho}{1 - \rho} = \rho^v. \quad (7.7)
\]
In Appendix A we also show that
\[
\begin{align*}
v &= 0, 1 : & \quad C_v(x) &= v/q \quad x = 1, 2, \ldots & \quad (7.8) \\
v &= 2 : & \quad C_v(1) &= \rho^2/p, \quad C_v(x) &= 1/q^2 \quad x = 2, 3, \ldots & \quad (7.9) \\
v &= 3, \ldots : & \quad C_v(x) &= \rho^v/p^x \quad x = 1, 2 & \quad (7.10a) \\
v &= 3, \ldots : & \quad C_v(x) &= \frac{1}{p} \sum_{j=0}^{x-1} \rho^v \quad x = 3, \ldots & \quad (7.10b)
\end{align*}
\]
Substituting (7.6)–(7.10) into (6.13), we obtain the solution \( h_v \) to the Poisson equation with forcing function \( c_v \) in the form
\[
h_v(x) = C_v(x) - J_vT(x) = C_v(x) - \rho^v x / q, \quad x \in S. \tag{7.11}
\]
Inspection of (7.7)–(7.10) reveals that \( C_v(x) \) is bounded in \( x \), and the solution \( h_v \) thus grows linearly is \( x \). Therefore, invoking Lemma 3.5 (in conjunction with (7.2)), we see that \( h_v \) is an element of \( \mathcal{U}_r \) and is therefore the unique solution in that class.

Using the Green decomposition technique of Section 4.2, we can identify a large class of forcing functions for which (7.3) will have a unique solution in \( \mathcal{U}_r \); details of the derivation are available in Appendix A.

**Theorem 7.1.** Consider the random walk with reflection at the origin defined through (7.1) with \( 0 < \rho < 1 \). Let \( c \) be a forcing function \( S \to \mathbb{R} \) such that \( |c(x)| \leq K(1 + r^x) \) for all \( x \) in \( S \), for some positive constants \( r \) and \( K \). If \( r \rho < 1 \), then the decomposition (4.7) (where \( (h_v, J_v) \) is given by (7.11) for all \( v \) in \( S \)) provides a solution \( (h, J) \) to the Poisson equation (2.5), and this solution is in \( \mathcal{U}_r \).

**8. BOUNDS AND EXTENSIONS**

In this section, we explore already some of the advantages afforded by the probabilistic representation (6.13). We use it to develop various bounds on the solution to the Poisson equation and to obtain an existence result for unbounded costs under a multichain structure.

**8.1. Bounds**

The following growth estimate is an easy consequence of the probabilistic representation (6.13).

**Theorem 8.1.** Assume the recurrence condition (R) to hold. If \( c \) is bounded, i.e., \( A := \sup_x |c(x)| < \infty \), then the solution pair \( (h, J) \) given by (6.13) satisfies the growth estimate
\[
|h(x)| \leq (A + J)T(x), \quad x \in S. \tag{8.1}
\]

Theorem 8.1 does not hold when \( c \) is not bounded. However, in many situations of interest, the underlying Markov chain is "skip-free to the left" with respect to \( z \). For example, in discrete-time queueing systems it is often the case that the decrease per unit time in the total number of customers is bounded above by the maximal number of available servers, say \( K \). As a result, with \( z \) representing the empty state, we obtain the relation \( |X_t| \leq KT, \ 0 \leq t \leq T \), where \( |X_t| \) denotes
the total number of customers at time \( t \), and \( T \) is here the time until the system empties. With this in mind, we introduce the following condition: There exists a positive constant \( K \) such that

\[
P_x[d(z, X_t) \leq KT, \quad 0 \leq t \leq T] = 1, \quad x \in S
\]  
(8.2)

for some metric \( d \) on \( S \). Under such a condition, the representation (6.13) implies the following bound.

**Theorem 8.2.** Assume both the recurrence condition \((R)\) and the integrability condition \((I)\) to hold. If the Markov chain satisfies (8.2), and if \( c \) exhibits the growth condition

\[
|c(x)| \leq A (1 + d(z, x) \delta), \quad x \in S
\]  
(8.3)

for positive constants \( A \) and \( \delta \), then the solution \( h \) given by (6.13) satisfies the growth estimate

\[
|h(x)| \leq B \left( T(x) + E_x \left[ T^{\delta+1} \right] \right), \quad x \in S \quad \text{where} \quad B = \max\{A + J, AK^\delta\}. \tag{8.4}
\]

In other words, the growth rate of \( h \) is determined by the growth rate of moments of \( T \). In particular, Theorem 8.2 shows how moments of recurrence times can be used to check that the solution (6.13) indeed belongs to \( \mathcal{B}_\mu \) or \( \mathcal{U}_\mu \) for some \( \mu \). Such information is of interest when studying the a.s. convergence of stochastic approximations schemes driven by Markov chains [1,20,17].

**Proof.** Note that (8.4) is automatically satisfied for \( x = z \) since then \( h(z) = 0 \). Now, fixing \( x \neq z \) in \( S \), we observe from the definition of \( C(x) \) that

\[
|C(x)| \leq E_x \left[ \sum_{t=0}^{T-1} |c(X_t)| \right] \leq AE_x \left[ \sum_{t=0}^{T-1} (1 + d(z, X_t) \delta) \right] \leq A \left( T(x) + E_x \left[ \sum_{t=0}^{T-1} (KT) \delta \right] \right) = A \left( T(x) + K^\delta E_x \left[ T^{\delta+1} \right] \right)
\]  
(8.5)

where the second and the third inequalities were obtained by making use of (8.3) and (8.2), respectively. The form of (6.13) now yields (8.4).

**8.2. Multiple classes**
When the state space contains several positive recurrent classes, it is convenient to use a decomposition of the state space \( S \) into its transient and recurrent components \( \{T_r, R_\alpha, \alpha \in A\} \), and to partition the Poisson equation accordingly. The treatment is similar to the one sketched briefly in [31].

With the decomposition and notation of Section 4, the results of the previous section extend to the multiple class case. For every \( \alpha \) in \( A \), select a state \( z_\alpha \) in \( R_\alpha \) and define the first passage times to the states \( z_\alpha, \alpha \in A \), and to the set \( Z := \{z_\alpha, \alpha \in A\} \) by

\[
T_\alpha := \inf\{t > 0 : X_t = z_\alpha\}, \quad \alpha \in A
\]

and

\[
T := \inf\{t > 0 : X_t \in Z\}.
\]

Since each recurrent class is closed under \( P \), at most one of the rvs \( \{T_\alpha, \alpha \in A\} \) is finite \( P_x \)-a.s. for each \( x \) in \( S \), so that

\[
T = \sum_\alpha T_\alpha 1[T_\alpha < \infty] \quad \text{on } [T < \infty] \quad P_x - \text{a.s.}
\]

under the convention \( 0 \cdot \infty = 0 \). For future use, we also define

\[
T_\alpha(x) := \mathbb{E}_x[T_\alpha 1[T_\alpha < \infty]], \quad \alpha \in A, \ x \in S.
\]

The appropriate version of condition (R) for the multiple class case is the finite mean condition

\[\text{(Rm) } \quad T(x) := \mathbb{E}_x[T] < \infty, \quad x \in S.\]

Note that (Rm) is essentially (R) but with the first passage time \( T \) defined through (8.8) rather than by (6.1). Under (Rm), it is plain that for each \( x \) in \( S \), \( T < \infty P_x \)-a.s. and that for each \( \alpha \) in \( A \), \( T_\alpha(x) = \mathbb{E}_x[T_\alpha] < \infty \) whenever \( x \) lies in \( R_\alpha \) with the implication that all recurrent states are positive recurrent. Condition (Rm) also implies that starting at any state \( x \) in \( S \), the process eventually reaches the recurrent classes and does so in finite expected time.

We now impose conditions (Rm) and (I) (with \( T \) defined through (8.8)). For every \( \alpha \) in \( A \), the following expressions

\[
C_\alpha(x) = \mathbb{E}_x \left[ \sum_{t=0}^{T_\alpha-1} c(X_t) \right], \quad x \in R_\alpha \quad \text{and} \quad J_\alpha := \frac{C_\alpha(z_\alpha)}{T_\alpha(z_\alpha)}
\]

are then well defined.
Theorem 8.3. Assume the recurrence condition (Rm) and the integrability conditions (I) to hold. If there exists a scalar \( J \) such that \( J_\alpha = J \) for all \( \alpha \) in \( A \), then the pair \((h, J)\) with \( h : S \to \mathbb{R} \) given by

\[
h(x) = C(x) - J \cdot T(x), \quad x \in S
\] (8.12)

is solution to the Poisson equation with the property that \( h(z) = 0 \) for every \( z \) in \( Z \).

Proof. The proof proceeds in two steps.

Step 1: First assume the set \( T_r \) of transient states to be empty. In that case the result follows readily from Theorem 6.3 if it can be shown that for each \( \alpha \) in \( A \), the pair \((h_{R_\alpha}, J_\alpha)\) is indeed a solution pair to the projected Poisson equation (4.5a) on \( R_\alpha \). That this is indeed the case can be seen as follows. The recurrence condition (Rm) implies that the restriction of the Markov chain \( P \) to the recurrence class \( R_\alpha \) satisfies the condition (R) imposed in the single recurrent case. Therefore, by Theorem 6.3 the projected Poisson equation (4.5a) on \( R_\alpha \) admits as solution the pair \((h_\alpha, J_\alpha)\) given by

\[
h_\alpha(x) = C_\alpha(x) - J_\alpha \cdot T_\alpha(x), \quad x \in R_\alpha
\] (8.13)

with \( J_\alpha \) given by (8.11). However, under (Rm) note that for \( x \) in \( R_\alpha \), \( T = T_\alpha < \infty \) \( P_x \)-a.s., whence \( T(x) = T_\alpha(x) \) and \( C(x) = C_\alpha(x) \). As a result, we find that \( J = J_\alpha = \frac{C_\alpha(x)}{T_\alpha(x)} = \frac{C_\alpha(x)}{T(x)} \), so that indeed \( h(x) = h_\alpha(x) \) for \( x \) in \( R_\alpha \).

Step 2: When \( T_r \) is not empty, the difficulty in obtaining a solution to the Poisson equation is related to the existence of transient states from which more than one recurrent class can be reached. First observe however that now (6.13)–(6.14) have to be replaced by

\[
T(x) = 1 + \sum_{y \notin \mathbb{Z}} p_{xy} T(y), \quad x \in S
\] (8.15)

and

\[
C(x) = c(x) + \sum_{y \notin \mathbb{Z}} p_{xy} C(y), \quad x \in S.
\] (8.16)

Therefore, in the same way that (6.13)–(6.14) lead to (6.16), it is easy to see that (8.15)–(8.16) imply

\[
[C(x) - J \cdot T(x)] + J = c(x) + \sum_{y \notin \mathbb{Z}} p_{xy} [C(y) - J T(y)]
\]

\[
= c(x) + \sum_{y} p_{xy} [C(y) - J \cdot T(y)], \quad x \in S
\] (8.17)

where the last step follows from the fact that \( C(z) = J \cdot T(z) \) for every \( z \) in \( Z \) as was noted in the first part of the proof. This time algebraic manipulations are validated through the summability
conditions
\[ \sum_{y \in \mathbb{Z}} p_{xy} T(y) < \infty \quad \text{and} \quad \sum_{y \in \mathbb{Z}} p_{xy} |C(y)| < \infty, \quad x \in S \] (8.18)
which follow from (8.15)–(8.16) and the integrability condition (I).

It is easy to see that in this case, (3.10b) also has a solution, using (3.10a) and the fact that for all \( x \in S \) and \( y \in R_\alpha \), the \( n \)-step transition probabilities \( p_{xy}^{(n)} \) each converge to \( P_x[T_\alpha < \infty] \cdot \nu^{(\alpha)}_y \) where \( \nu^{(\alpha)} \) is the invariant distribution of the Markov chain \( P \) when restricted to \( R_\alpha \).

9. PARAMETRIC DEPENDENCE: CONTINUITY

In several applications, including stochastic adaptive control and stochastic approximations [1, 3, 13, 17, 19, 20], the analysis simultaneously deals with a parameterized family of Markov chains, rather than a single Markov chain, and crucial to the arguments is the smoothness (in the parameter) of solutions to the associated Poisson equations. Of particular interest are conditions on the model data which guarantee that the solution to the Poisson equation is continuous, or even Lipschitz continuous in the parameter. It is the purpose of this and the next sections to show how the representation results of Sections 6 and 8 provide a natural vehicle to explore this question. Our intent is not to get the best possible results, but rather to suggest ways of attacking these parametric issues.

In order to simplify the notation, the discussion is given only for the case of a scalar parameter set, as similar arguments can be developed mutatis mutandis for more general situations: Let the parameter set \( \Theta \) be a Borel subset of \( \mathbb{R} \), and consider a family \( \{ P(\theta), \ \theta \in \Theta \} \) of one-step transition probability matrices on the countable set \( S \), with \( P(\theta) \equiv (p_{xy}(\theta)) \). For every \( \theta \) in \( \Theta \) and \( x \) in \( S \), let \( P^\theta_x \) and \( E^\theta_x \) denote the probability measure and corresponding expectation operator induced on \( (\Omega, \mathcal{F}) \) by \( P(\theta) \) given that \( X_0 = x \).

The set-up is the one of Section 6. There exists a distinguished state \( z \) in \( S \) such that for all \( \theta \) in \( \Theta \),
\[ T(\theta, x) := E^\theta_x [T] < \infty, \quad x \in S \] (9.1)
with \( T \) still denoting the first passage time (6.1) to the state \( z \). In other words, the recurrence condition (R) holds with respect to the same point \( z \) independently of \( \theta \).

For every \( \theta \) in \( \Theta \), a given mapping \( c(\theta) : S \to \mathbb{R} : x \to c(\theta, x) \) is assumed to drive the Poisson equation (2.5) associated with \( P(\theta) \), i.e.,
\[ h + J = c(\theta)e + P(\theta)h. \] (9.2)
For all $\theta$ in $\Theta$, the integrability condition (I)

$$
E_x^\theta \left[ \sum_{t=0}^{T-1} |c(X_t)| \right] < \infty, \quad x \in S
$$

(9.3)

is assumed to hold. Under the enforced assumptions, we may invoke Theorem 6.3 to conclude that (9.2) admits at least one solution $(h(\theta), J(\theta))$ where $J(\theta)$ is a scalar and $h(\theta)$ is a mapping $S \to \mathbb{R}: x \to h(\theta, x)$.

With the requirement $h(\theta, z) = 0$, this solution $(h(\theta), J(\theta))$ has the representation

$$
J(\theta) = \frac{C(\theta, z)}{T(\theta, z)} \quad \text{and} \quad h(\theta, x) = C(\theta, x) - J(\theta) \cdot T(\theta, x), \quad x \in S.
$$

(9.4)

The next result identifies a set of natural conditions for establishing continuity of solutions to (9.2).

Such a regularity property was required, for example in [3].

**Theorem 9.1.** Under the foregoing conditions, suppose that for each $x$ in $S$,

(i) the mapping $\theta \to c(\theta, x)$ is continuous on $\Theta$;

(ii) the mapping $\theta \to p_{xy}(\theta)$ is continuous over $\Theta$ for all $y$ in $S$;

(iii) the family of probability measures $\{p_x(\theta), \theta \in \Theta\}$ on $S$ is tight;

(iv) the rvs $\{(T, P_x^\theta), \theta \in \Theta\}$ are uniformly integrable; and

(v) the rvs $\{(\sum_{t=0}^{T-1} |c(\theta, X_t)|, P_x^\theta), \theta \in \Theta\}$ are uniformly integrable.

Then for every $x$ in $S$, the mappings $\theta \to T(\theta, x)$ and $\theta \to C(\theta, x)$ are continuous over $\Theta$.

In many applications, $c(\theta, x) = c(x)$ for all $x$ in $S$ and $\theta$ in $\Theta$ so that (i) automatically holds, while (iii) is satisfied whenever one-step transitions have some uniform (in $\theta$) nearest-neighbor properties. The conditions (iv)–(v) are usually checked by (stochastically) bounding the original system uniformly in $\theta$ by means of another system which is naturally suggested by the original system. This approach was taken by Rosberg and Makowski in [25].

The next two lemmas are needed in the proof of Theorem 9.1; their proof can be found in Appendix B.

**Lemma 9.2.** Assume (ii)–(iii) of Theorem 9.1. For all $x$ and $y$ in $S$, and $k = 1, 2, \ldots$, the mappings $\theta \to P^\theta_x[T = k]$ and $\theta \to P^\theta_x[X_t = y, T = k], 1 \leq t < k$, are all continuous on $\Theta$.

**Lemma 9.3.** Assume (iii) of Theorem 9.1. For each $t = 1, 2, \ldots$ and $x$ in $S$, the family of distributions $\{(X_t, P^\theta_x), \theta \in \Theta\}$ is tight.
To prepare the proof of Theorem 9.1, we set

\[ C_m(\theta, x) := \mathbb{E}^\theta_x \left[ \mathbf{1}[T \leq m] \sum_{t=0}^{T \wedge m - 1} c(\theta, X_t) \right], \quad x \in S. \quad m = 1, 2, \ldots (9.6) \]

**Proof of Theorem 9.1.** Let \( x \) be a fixed element in \( S \). By a standard decomposition argument, there is no loss of generality in assuming \( c(\theta, x) \geq 0 \) for all \( x \) in \( S \) and \( \theta \) in \( \Theta \). Moreover the first claim follows from the second one upon using \( c(\theta, x) \equiv 1 \).

In the general case, standard facts from analysis [27] imply the desired continuity result if it can be established that the mappings \( \theta \rightarrow C_m(\theta, x), \ m = 1, 2, \ldots, \) are continuous on \( \Theta \), and then that the convergence \( \lim_m C_m(\theta, x) = C(\theta, x) \) is uniform in \( \theta \).

To establish the first step, it suffices to show that the mappings \( \theta \rightarrow \mathbb{E}^\theta_x[\mathbf{1}[T = k]c(\theta, X_t)], \ 0 \leq t < k, \) are continuous for (9.6) can be written as

\[ C_m(\theta, x) = \sum_{k=1}^{m} \sum_{t=0}^{k-1} \mathbb{E}^\theta_x[\mathbf{1}[T = k]c(\theta, X_t)]. \quad m = 1, 2, \ldots (9.7) \]

Fix \( 0 \leq t < k \). Because the rvs \( \{(X_t, P^\theta_x), \ \theta \in \Theta\} \) are tight by Lemma 9.3, for every \( \delta > 0 \) there exists a finite subset \( G_x(\delta) \) of \( S \) such that \( \sup_{\theta \in \Theta} P^\theta_x[X_t \notin G_x(\delta)] < \delta \). Therefore the easy bound

\[ \mathbb{E}^\theta_x[\mathbf{1}[T = k]1[X_t \notin G_x(\delta)]c(\theta, X_t)] \leq \mathbb{E}^\theta_x \left[ \mathbf{1}[X_t \notin G_x(\delta)] \sum_{s=0}^{T-1} c(\theta, X_s) \right] \]

and the uniform integrability condition (v) together imply that for every \( \varepsilon > 0 \) there exists some \( \delta(\varepsilon) > 0 \) such that

\[ \sup_\theta \mathbb{E}^\theta_x[\mathbf{1}[T = k]1[X_t \notin G_x(\delta(\varepsilon))]c(\theta, X_t)] \leq \varepsilon. \quad (9.9) \]

On the other hand, the mapping \( \theta \rightarrow \mathbb{E}^\theta_x[\mathbf{1}[T = k]1[X_t \in G_x(\delta(\varepsilon))]c(\theta, X_t)] \) is continuous by virtue of Lemma 9.2 since \( G_x(\delta(\varepsilon)) \) is finite. The desired continuity of the mapping \( \theta \rightarrow \mathbb{E}^\theta_x[\mathbf{1}[T = k]c(\theta, X_t)] \) readily follows from this remark and from (9.9) by using a standard decomposition argument. Details are left to the interested reader.

For the second step, start with the estimate

\[ 0 \leq C(\theta, x) - C_m(\theta, x) = \mathbb{E}^\theta_x \left[ \mathbf{1}[m < T] \sum_{t=0}^{T-1} c(\theta, X_t) \right]. \quad m = 1, 2, \ldots (9.10) \]
and observe that the uniform integrability of the rvs \( \{ (T, P^\theta_x), \theta \in \Theta \} \) yields \( \lim_m \sup \theta P^\theta_x [T > m] = 0 \). This fact and the uniform integrability condition (v) immediately imply the uniform convergence

\[
\lim_m \sup \theta \mathbb{E}^\theta_x \left[ 1_{[m < T]} \sum_{t=0}^{T-1} c(\theta, X_t) \right] = 0 \quad (9.11)
\]

and the proof is now complete.

\[\Box\]

10. PARAMETRIC DEPENDENCE: LIPSCHITZ CONTINUITY

Metivier and Priouret [20] have shown that the a.s. convergence of stochastic approximations passes through the Lipschitz continuity of solutions \( (h(\theta), J(\theta)) \) to the parametrized Poisson equation (9.2). Arguments for establishing such Lipschitz continuity are now outlined in a somewhat restricted setup which often occurs in applications [13, 17]. To that end, we postulate that for all \( x \) in \( S \), the probability measures \( \{ p^\theta_x, \theta \in \Theta \} \) on \( S \) are mutually absolutely continuous, i.e., if \( p^y_x(\theta) = 0 \) for some \( y \) in \( S \) and \( \theta \) in \( \Theta \), then \( p^y_x(\theta') = 0 \) for all \( \theta' \) in \( \Theta \). As a result, for each \( m = 1, 2, \ldots, \) the probability measures \( \{ P^\theta_x, \theta \in \Theta \} \) are mutually absolutely continuous on the \( \sigma \)-field \( \mathcal{F}_m \). If \( L^\theta_m(\theta, \theta') \) denotes the Radon–Nikodym derivative of \( P^\theta_x \) with respect to \( P^\theta_x \) (on \( \mathcal{F}_m \)), then

\[
L^\theta_m(\theta, \theta') = \prod_{j=0}^{m-1} \frac{p^j_{X_t X_{t+1}}(\theta')}{p^j_{X_t X_{t+1}}(\theta)} \quad m = 1, 2, \ldots (10.1)
\]

where the convention \( \frac{0}{0} = 0 \) is adopted. With \( L^\theta_0(\theta, \theta') = 1 \), the rvs \( \{ L^\theta_m(\theta, \theta'), m = 0, 1, \ldots \} \) form a \( (P^\theta_x, \mathcal{F}_m) \)-martingale, and for any non-negative \( \mathcal{F}_{T\wedge m} \)-measurable rv \( X \),

\[
\mathbb{E}^\theta_x [X] = \mathbb{E}^\theta_x [L^\theta_m(\theta, \theta') \cdot X] \quad m = 0, 1, \ldots (10.2)
\]

by standard results on absolutely continuous changes of measures [6].

**Theorem 10.1.** Under the foregoing conditions, suppose there exist a constant \( K > 0 \) and a mapping \( S \to (0, \infty) : x \to K(x) \) such that for all \( \theta \) and \( \theta' \) in \( \Theta \),

\[
|p^y_x(\theta) - p^y_x(\theta')| \leq K p^y_x(\theta) \cdot |\theta - \theta'|, \quad x, y \in S \quad (10.3)
\]

and

\[
|c(\theta, x) - c(\theta', x)| \leq K(x) \cdot |\theta - \theta'|, \quad x \in S. \quad (10.4)
\]

If the moment conditions

\[
\tilde{K}(x) := \sup \theta \mathbb{E}^\theta_x \left[ \sum_{i=0}^{T-1} K(X_i) \right] < \infty, \quad x \in S \quad (10.5)
\]

and
\[ \tilde{C}(x) := \sup_{\theta} \mathbb{E}_x^\theta \left[ T (1 + \delta)^T \sum_{t=0}^{T-1} |c(\theta, X_t)| \right] < \infty, \quad x \in S \] (10.6)

are satisfied for some \( 0 < \delta \leq 1 \), then for every \( x \) in \( S \), the mappings \( \theta \rightarrow C(\theta, x) \) are locally Lipschitz continuous over \( \Theta \). In fact, whenever \( |\theta - \theta'| \leq \frac{\delta}{K} \), the Lipschitz estimates

\[ |C(\theta, x) - C(\theta', x)| \leq L(x)|\theta - \theta'|, \quad x \in S \] (10.7)

hold with \( L(x) := K\tilde{C}(x) + \tilde{K}(x) \) for all \( x \) in \( S \).

A few observations are in order before giving a proof of Theorem 10.1: A result on the Lipschitz continuity of the mappings \( \theta \rightarrow T(\theta, x) \), \( x \) in \( S \), is readily obtained from Theorem 10.1 upon using \( c(\theta, x) \equiv 1 \), in which case conditions (10.4)–(10.5) are automatically satisfied, and (10.6) reduces to

\[ \tilde{T}(x) := \sup_{\theta} \mathbb{E}_x^\theta \left[ T^2 (1 + \delta)^T \right] < \infty, \quad x \in S. \] (10.8)

In fact, (10.6) also reduces to (10.8) whenever the cost function is bounded, i.e., \( |c(\theta, x)| \leq B \) for all \( x \) in \( S \) and \( \theta \) in \( \Theta \).

When the Lipschitz constant in (10.4) does not depend on \( x \), i.e., \( K(x) = K \) for all \( x \) in \( S \), then (10.5) reduces to the condition \( \sup_{\theta} \mathbb{E}_x^\theta [T] < \infty \) for all \( x \) in \( S \).

The uniform bounds (10.8) can be checked in a variety of ways. For instance, in [15, 16, 17, 29] the authors considered a particular model where the distribution of the first passage time \( T \) under \( P_x^\theta \) is independent of \( \theta \) – of course a rare occurrence – so that (10.8) becomes a simple moment requirement. Some general methods are sketched in [17]. In other situations, specific arguments have to be developed, as we now do under the assumption that for some distinguished \( \theta^* \) in \( \Theta \), there exists a constant \( B > 0 \) such that for all \( \theta \) in \( \Theta \),

\[ \frac{p_{xy}(\theta)}{p_{xy}(\theta^*)} \leq B \quad \text{whenever} \quad p_{xy}(\theta^*) > 0, \quad x, y \in S. \] (10.9)

In that case, fixing \( \theta \) in \( \Theta \) and \( x \) in \( S \), we observe from (10.2) that

\[ \mathbb{E}_x^\theta [1[T \leq m] (T \wedge m)] \leq \mathbb{E}_x^{\theta^*} [1[T \leq m](T \wedge m) \cdot B^{T\wedge m}] \] (10.10)

because \( 0 \leq L^T_{T \wedge m}(\theta^*, \theta) \leq B^{T\wedge m} \) by virtue of (10.9), whence \( \mathbb{E}_x^\theta [T] \leq \mathbb{E}_x^{\theta^*} [T \cdot B^T] \) by a simple limiting argument. The same reasoning shows that \( \mathbb{E}_x^\theta [T^2 (1 + \delta)^T] \leq \mathbb{E}_x^{\theta^*} [T^2((1 + \delta)B)^T]. \)
Consequently (10.8) holds under the structural condition (10.9) if the more compact conditions
\[ \mathbb{E}_x^\theta \left[ T^2((1 + \delta)B)T \right] < \infty \]
holds.

**Proof of Theorem 10.1.** Let \( x \) be a fixed element in \( S \). As in the proof of Theorem 9.1, there is no loss of generality in assuming \( c(\theta, x) \geq 0 \) for all \( x \) in \( S \) and \( \theta \) in \( \Theta \).

Fix \( \theta \) and \( \theta' \) in \( \Theta \). It is easily seen from (9.6) and (10.2) that
\[
C_m(\theta', x) := \mathbb{E}_x^\theta \left[ 1[T \leq m] \cdot L_{T \wedge m}^2(\theta, \theta') \sum_{t=0}^{T \wedge m - 1} c(\theta', X_t) \right]. \quad m = 1, 2, \ldots (10.11)
\]

With this relation in mind, we define
\[
A_m(\theta, \theta') := \mathbb{E}_x^\theta \left[ 1[T \leq m] \cdot [1 - L_{T \wedge m}^2(\theta, \theta')] \cdot \sum_{t=0}^{T \wedge m - 1} c(\theta, X_t) \right] \quad (10.12)
\]
and
\[
B_m(\theta, \theta') := \mathbb{E}_x^\theta \left[ 1[T \leq m] \cdot L_{T \wedge m}^2(\theta, \theta') \cdot \left[ \sum_{t=0}^{T \wedge m - 1} c(\theta, X_t) - \sum_{t=0}^{T \wedge m - 1} c(\theta', X_t) \right] \right] \quad (10.13)
\]
for all \( m = 1, 2, \ldots \), so that \( C_m(\theta, x) - C_m(\theta', x) = A_m(\theta, \theta') + B_m(\theta, \theta') \) for \( m = 0, 1, \ldots \).

Condition (10.3) implies
\[
\left| 1 - \frac{p_{xy}(\theta')}{p_{xy}(\theta)} \right| \leq K \cdot |\theta - \theta'| \quad \text{whenever} \quad p_{xy}(\theta) > 0, \quad x, y \in S, \quad (10.14)
\]
so that on the event \([L_{T \wedge m}^2(\theta, \theta') > 0]\), provided \( K|\theta - \theta'| < 1\),
\[
(1 - K|\theta - \theta'|)^{T \wedge m} - 1 \leq L_{T \wedge m}^2(\theta, \theta') - 1 \leq (1 + K|\theta - \theta'|)^{T \wedge m} - 1. \quad m = 1, 2, \ldots (10.15)
\]
From the easy identities
\[
(1 \pm Kt)^m - 1 = \int_0^t (\pm mK) \cdot (1 \pm K\tau)^{m-1} d\tau, \quad t > 0 \quad m = 1, 2, \ldots (10.16)
\]
we conclude
\[
\left| (1 \pm Kt)^{T \wedge m} - 1 \right| \leq K(T \wedge m) \cdot (1 + \delta)^{T \wedge m} \cdot t \quad m = 1, 2, \ldots (10.17)
\]
whenever \( 0 < t \leq \frac{\delta}{K} \) (where \( 0 < \delta \leq 1 \)). Therefore, upon combining (10.15) and (10.17), under the condition \( K|\theta - \theta'| < \delta \) we find
\[
|A_m(\theta, \theta')| \leq K \cdot \mathbb{E}_x^\theta \left[ 1[T \leq m] \cdot (T \wedge m) \cdot (1 + \delta)^{T \wedge m} \cdot \sum_{t=0}^{T \wedge m - 1} c(\theta, X_t) \right] \cdot |\theta - \theta'| \]
for all \( m = 1, 2, \ldots \), and a simple limiting argument yields

\[
\lim_m |A_m(\theta, \theta')| \leq K \cdot E^\theta_x \left[ T \cdot (1 + \delta)^T \cdot \sum_{t=0}^{T-1} c(\theta, X_t) \right] \cdot |\theta - \theta'|. \tag{10.18}
\]

On the other hand, we have

\[
|B_m(\theta, \theta')| \leq E^\theta_x \left[ 1[1 \leq m] \cdot L^\alpha_{T^m}(\theta, \theta') \cdot \sum_{t=0}^{T^m-1} |c(\theta, X_t) - c(\theta', X_t)| \right]
\leq E^\theta_x \left[ 1[1 \leq m] \cdot L^\alpha_{T^m}(\theta, \theta') \cdot \sum_{t=0}^{T^m-1} K(X_t) \right] \cdot |\theta - \theta'|
= E^{\theta'}_x \left[ 1[1 \leq m] \cdot \sum_{t=0}^{T^m-1} K(X_t) \right] \cdot |\theta - \theta'| \quad m = 1, 2, \ldots \tag{10.19}
\]

where the second inequality is a consequence of (10.4), and the final equality follows from (10.2). Consequently, in the limit, we conclude that

\[
\lim_m |B_m(\theta, \theta')| \leq E^{\theta'}_x \left[ \sum_{t=0}^{T} K(X_t) \right] \cdot |\theta - \theta'| \tag{10.20}
\]

and the result now readily follows from (10.18) and (10.20).

**Acknowledgment:** We are indebted to an anonymous referee for pointing out reference [7].

**APPENDIX A: THE EXAMPLE**

To obtain (7.6) from (7.2), we apply (6.17) with \( z = 0 \) to get

\[
T(x) = 1 + pT(x + 1), \quad x = 0, 1 \quad (A.1)
\]

and

\[
T(x) = 1 + pT(x + 1) + qT(x - 1). \quad x = 2, 3, \ldots \quad (A.2)
\]

Since \( T(0) = 1/\gamma(0) \) by standard results on Markov chains, we can use (7.2) to obtain (7.6). Indeed, the validity of (7.6) can be seen by substituting \( T(0) \) into (A.1)–(A.2), so that \( T(3) - T(2) = T(2) - T(1) \). Using (A.2), we see that this last equality propagates by induction, i.e., \( T(x + 1) - T(x) = T(x) - T(x - 1) \) for all \( x = 2, \ldots \) and (7.6) readily follows.
Fixing $v$ in $S$, we now set out to compute the cost per cycle $C_v$ associated with $c_v$. To do so, we use the system of equations (6.16) which here takes the form

$$C_v(x) = c_v(x) + pC_v(x+1), \quad x = 0, 1 \quad (A.4)$$

and

$$C_v(x) = c_v(x) + pC_v(x+1) + qC_v(x-1), \quad x = 2, 3, \ldots \quad (A.5)$$

For $v = 0, 1$ or $v = 2$, we use (A.4)–(A.5) to get (7.8)–(7.9) by straightforward calculations. The case $v \geq 3$ is more involved: We observe that $C_v(x) = C_v(x+1)$, $x = v, \ldots$ which is readily derived from the definition of $C_v$ (which holds for $v \geq 1$). Moreover, as the relation (A.5) implies

$$p(C_v(x+1) - C_v(x)) = q(C_v(x) - C_v(x-1)), \quad x = 2, \ldots, v - 1 \quad (A.6)$$

we conclude that

$$C_v(x+1) = (C_v(x+1) - C_v(x)) + (C_v(x) - C_v(x-1)) + \ldots + (C_v(2) - C_v(1)) + C_v(1)$$

$$= \sum_{j=0}^{x-1} \rho^{-j} (C_v(j) - C_v(1)) + C_v(1), \quad x = 2, \ldots, v - 1. \quad (A.7)$$

Because $c_v(0) = c_v(1) = 0$, we obtain (7.10a) from (7.7) and (A.4), and combining this last relationship with (A.7), we finally get (7.10b) after some algebra.

**Proof of Theorem 7.1.** First, we observe from (A.3) and the hypothesis that

$$\sum_{v=0}^{\infty} |c(v)| J_v \leq K \sum_{v=0}^{\infty} (1 + r^v)(1 - \rho)\rho^v < \infty \quad (A.8)$$

because $\rho < 1$ and $r \rho < 1$, and the quantity $J$ given by (4.7) is therefore well defined. Next, using (7.6), and the fact $\rho < 1$, we see that

$$\sum_{x=0}^{\infty} \gamma(x) T(x) = 1 + \frac{\rho}{q(1 - \rho)^2} < \infty. \quad (A.8)$$

Finally, we claim that

$$\sum_{x=0}^{\infty} \gamma(x) \sum_{v=0}^{\infty} |c(v)| C_v(x) < \infty. \quad (A.10)$$
Before giving a proof, we combine (A.10) with (4.7) and (A.9) to conclude that for each \( x \) in \( S \), the quantity \( h(x) \) given by

\[
h(x) := \sum_{\nu=0}^{\infty} c(\nu)h_\nu(x) = \sum_{\nu=0}^{\infty} c(\nu)[C_\nu(x) - J_\nu T(x)] = \sum_{\nu=0}^{\infty} c(\nu)C_\nu(x) - JT(x)
\]  

(A.11)

is well defined since all infinite series are absolutely convergent.

To establish (A.10), we first interchange the order of summation (by a simple application of Tonelli’s Theorem), and note that

\[
\sum_{x=0}^{\infty} \gamma(x) \sum_{\nu=0}^{\infty} |c(\nu)|C_\nu(x) \leq K \sum_{\nu=0}^{\infty} (1 + r^\nu) \sum_{x=0}^{\infty} \gamma(x)C_\nu(x) = K(1 - \rho) \sum_{\nu=0}^{\infty} (1 + r^\nu) \sum_{x=0}^{\infty} \rho^x C_\nu(x).
\]  

(A.12)

The fact that the right hand side of (A.12) is finite follows from (7.8)–(7.10) once we observe that for \( \nu = 3, 4, \ldots \), the bounds

\[
C_\nu(x) \leq \begin{cases} 
\rho^\nu, & x = 0 \\
C \rho^{\nu-x}(1 - \rho^x), & x = 1, \ldots, \nu \\
C(1 - \rho^\nu), & x = \nu, \nu + 1, \ldots
\end{cases}
\]  

(A.13)

hold for some positive constant \( C \) which depends only on \( \rho \). The calculations are tedious and are omitted; the finiteness of the various infinite series follows from the fact that \( \rho < 1 \) and \( r \rho < 1 \).

Combining (A.9) and (A.10) with (A.11) we see that \( h \) defined by (A.11) belongs to \( B_\gamma = U_\gamma \). As the Poisson equation (3.1) involves here only a finite sum, it is immediate by substitution that under the stated conditions, the pair \((h, J)\) defined above is indeed a solution to (3.1) since for each \( \nu \) in \( S \), the pair \((h_\nu, J_\nu)\) is a solution to the Poisson equation.

\[ \blacksquare \]

**APPENDIX B: PROOFS OF LEMMAS 9.2–9.3**

**Proof of Lemma 9.2.** Both parts are proved along similar induction arguments. For the first part, since \( P_\theta^\tau[T = 1] = p_{xx}(\theta) \) for all \( x \) in \( S \), the assumption (ii) implies the continuity of the mapping \( \theta \rightarrow P_\theta^\gamma[T = k] \) for \( k = 1 \). The induction argument will propagate through the relations

\[
P_\theta^\gamma[T = k + 1] = \sum_{y \neq x} p_{xy}(\theta)P_\theta^\gamma[T = k], \quad x \in S \quad k = 1, 2, \ldots \quad (B.1)
\]
which are simple consequences of the Markov property for all \( \theta \) in \( \Theta \). Indeed, fix \( x \) in \( S \) and assume that for some \( k = 1, 2, \ldots \), the mapping \( \theta \rightarrow P^\theta_y[T = k] \) is continuous for all \( y \) in \( S \). By the tightness condition (iii), for every \( \varepsilon > 0 \), there exists a finite subset \( F_\varepsilon \) of \( S \setminus \{z\} \) such that

\[
\sup_{\theta \in \Theta} \left[ \sum_{y \not\in F_\varepsilon} p_{xy}(\theta) \right] < \varepsilon. \tag{B.2}
\]

It is now plain from (B.1)–(B.2) that for all \( \theta \) and \( \theta' \) in \( \Theta \),

\[
|P^\theta_x[T = k + 1] - P^{\theta'}_x[T = k + 1]| \leq 2\varepsilon + \sum_{y \in F_\varepsilon} \left| p_{xy}(\theta)P^\theta_y[T = k] - p_{xy}(\theta')P^{\theta'}_y[T = k] \right| \tag{B.3}
\]

and therefore \( \lim_{\theta' \to \theta} |P^\theta_x[T = k + 1] - P^{\theta'}_x[T = k + 1]| \leq 2\varepsilon \) by invoking (ii), the induction hypothesis and the finiteness of \( F_\varepsilon \). The continuity of \( \theta \rightarrow P^\theta_x[T = k + 1] \) follows.

For the second part of the lemma, only the case \( y \neq z \) needs to be considered for otherwise the result is trivially true since \( P^\theta_x[X_t = z, T = k] = 0 \) on \( \Theta \) for all \( x \) in \( S \) whenever \( 1 \leq t < k \). Thus, for all \( \theta \) in \( \Theta \), set

\[
q^\theta(x; t, y) := P^\theta_x[X_s \neq z, 1 \leq s < t, X_t = y], \quad x, y \in S \quad t = 1, 2, \ldots \tag{B.4}
\]

and observe from the Markov property that for all \( x \) and \( y \neq z \) in \( S \),

\[
P^\theta_x[X_t = y, T = k] = P^\theta_y[T = k - t] \cdot q^\theta(x; t, y), \quad 1 \leq t < k. \tag{B.5}
\]

Therefore, by the first part of the proof, it suffices to show that the mappings \( \theta \rightarrow q^\theta(x; t, y) \), \( t = 1, 2, \ldots \), are all continuous as \( x \) and \( y \) range over \( S \). This is done again by induction. Fix \( y \) in \( S \) and observe that for all \( x \) in \( S \), the continuity of \( \theta \rightarrow q^\theta(x; t, y) \) readily follows from (ii) for \( t = 1 \), since \( q^\theta(x; 1, y) = P^\theta_x[X_1 = y] = p_{xy}(\theta) \). Now assume that for some \( t = 1, 2, \ldots \) the mappings \( \theta \rightarrow q^\theta(v; t, y) \) are continuous for all \( v \) in \( S \). The relations \( q^\theta(x; t + 1, y) = \sum_{v \neq x} p_{xy}(\theta) \cdot q^\theta(v; t, y) \) hold for \( x \) in \( S \) and \( t = 1, 2, \ldots \); they are simple consequences of the Markov property, and can be used to propagate the induction as in the first part of the proof. Details are left to the interested reader. \( \blacksquare \)

**Proof of Lemma 9.3.** The proof is again by induction. Let \( x \) be a given element of \( S \), and note that for \( t = 1 \) the result is true by assumption since the tightness of \( \{(X_1, P^\theta_x), \theta \in \Theta\} \) is nothing but (iii). To proceed further, observe from the Markov property that for every finite set \( F \) of \( S \),

\[
P^\theta_x[X_{t+1} \not\in F] = \sum_y p_{xy}(\theta)P^\theta_y[X_t \not\in F], \quad x \in S, \quad t = 1, 2, \ldots \tag{B.6}
\]
Now assume that for some \( t = 1, 2, \ldots \), the rvs \( \{X_t, P^\theta_y\}, \theta \in \Theta \) are tight for each \( y \) in \( S \), in which case for every \( \delta > 0 \), there exists a finite subset \( G_y(\delta) \) of \( S \) such that \( \sup_{\theta \in \Theta} P^\theta_y[X_t \not\in G_y(\delta)] < \delta \), for \( y \in S \). As in the proof of Lemma 9.2, let \( F_\varepsilon \) be the finite subset of \( S \) guaranteed by (iii) such that (B.2) holds, and set \( G(\varepsilon, \delta) = \bigcup_{y \in F_\varepsilon} G_y(\delta) \). It is plain that

\[
\sup_{\theta \in \Theta} \sum_{y \in F_\varepsilon} p_{xy}(\theta) P^\theta_y[X_t \not\in G(\varepsilon, \delta)] < \delta \tag{B.7}
\]

while the defining property of \( F_\varepsilon \) implies

\[
\sup_{\theta \in \Theta} \sum_{y \not\in F_\varepsilon} p_{xy}(\theta) P^\theta_y[X_t \not\in G(\varepsilon, \delta)] < \varepsilon. \tag{B.8}
\]

Combining (B.6) with (B.7)–(B.8) leads to \( \sup_{\theta \in \Theta} P^\theta_{x}[X_{t+1} \not\in G(\varepsilon, \delta)] < \varepsilon + \delta \) and this completes the proof since \( \varepsilon \) and \( \delta \) are arbitrary.
